

APPLICATION FOR UNITED STATES LETTERS PATENT

TITLE:        **SYSTEM AND METHOD FOR  
CAPTURING AND SEARCHING  
IMAGE DATA ASSOCIATED  
WITH TRANSACTIONS**  
INVENTOR: **JEFFERY M. ENRIGHT, ET AL.**  
DOCKET NO: **D-1112R2**

## TECHNICAL FIELD

This invention relates to transaction record systems. Specifically this invention relates to a transaction record system for an automated banking machine which provides image records as well as data records related to transactions and other activities. The invention further relates to a system which captures images and enables images and data to be stored, remotely accessed and selectively processed and analyzed.

## BACKGROUND ART

Automated banking machines are known in the prior art. A common type of automated banking machine used by consumers is an automated teller machine ("ATM"). ATMs enable customers to carry out banking transactions such as dispensing cash, making deposits, making transfers of funds, depositing checks and other instruments, payment of bills and account balance inquiries. Other types of automated banking machines are used for purposes of dispensing tickets, scrip, travelers checks, airline tickets, gaming materials and other items of value. Other types of automated banking machines are used by service providers such as cashiers or bank tellers for purposes of dispensing or receiving currency, counting currency and determining the genuineness of currency. For purposes of this disclosure an automated banking machine will be considered as being any machine which accomplishes the handling or transfer of items having or representative of value.

In the past some automated banking machines have included a camera system. Cameras have been installed adjacent to the machine for purposes of viewing persons conducting transactions. Such cameras have been connected to video tape recorders and record an image of the customer conducting the transaction. Such systems have limitations because the tapes used to

record the images must be periodically changed. A failure to change the tape could result in images no longer being recorded. Changing the tape too soon results in a waste of available image storage space. Tapes that are reused wear out after a few cycles.

5 A further drawback associated with tape recording systems used in connection with automated banking machines is that the tapes should be maintained for a substantial period. For example if a customer claims that they did not conduct a transaction, this will likely not be known until several weeks or months after the transaction was conducted. To determine if the customer's assertions are true the tape must be located. This involves cataloguing and storing tapes, often for extended periods of time. This is inconvenient and costly.

10 A further drawback associated with conventional image recording systems associated with automated banking machines is that the camera may be blocked. Such blocking may be deliberate or inadvertent. For example a criminal wishing to avoid identification may cover the lens area of the camera so that no usable video is obtained. Alternatively, lighting conditions such as sun glare and shadows may render a camera unable to provide a suitable video image.

15 A further limitation of existing ATM camera systems is that they often record only a single image during the transaction. If that image happens to coincide with a time when the customer is not facing in a direction which enables the camera can take a suitable picture, the image is of no value. Alternatively, if a camera is operated to record throughout every transaction the available tape supply will be used up more quickly. In such situations the tape  
20 supply is often consumed by recording images of persons withdrawing very small amounts from the ATM.

A further issue that sometimes arises with regard to automated banking machines is shortages of materials or cash. Sometimes for example, the amount of cash remaining within a machine is less than available records suggest should be held therein. Similar issues may arise with other items that are dispensed from or deposited in automated banking machines. Such issues call into question whether there has been a machine malfunction, conversion by a person authorized to service the machine or theft by a third party. As servicers such as bank employees accessing automated banking machines are often unsupervised, it is sometimes impossible to determine the cause of the shortage.

Circumstances sometimes arise in the course of transactions at automated banking machines where it would be desirable to inform particular individuals of the existence of the circumstances. Such circumstances may include for example that the recording media being used to record images needs to be changed. Other conditions may include that someone has gained access to the machine or an area surrounding the machine. It would be desirable to include an image with or as part of some messages. Such information would enable persons who need to know about such conditions to take immediate action.

Certain types of automated banking machines also accept documents representative of value such as checks and travelers checks. Often issues arise concerning the authenticity of such items. Determining the authenticity of such items may be a time consuming process due to the need to physically retrieve such items and to compare indicia thereon to a genuine item. An example would be signature comparisons for determining whether a particular signature is appropriate. Such activities can be costly and time consuming.

There further exists a need for systems that operate so that when a triggering event occurs, the capture of images and other actions occur in a predetermined sequence. For example the occurrence of an image condition such that motion is sensed by a camera or that the camera is blocked, may cause additional images to be captured from the same or other cameras. In such  
5 circumstances images taken prior to the triggering event may be stored in correlated relation with the images corresponding to the event for a later analysis. In some circumstances it may be desirable to have images captured at different rates based on the nature of the triggering events, including at rates which comprise generally continuous image video capture. There further exists a need for systems in which a triggering event may consist of a change within a particular  
10 detection area, which is a subset of an entire image being viewed by a camera. This enables actions to be taken in response to changes in the detection area while other changes within the field of view may be ignored. There further exists a need to program an image capture system with such sequences in a simplified manner.

There further exists a need for systems in which captured images can be stored and  
15 analyzed. This may include for example analysis by the type of triggering event which caused the image to be captured. Other parameters for searching images would also be desirable to use, such as the content of the image, the type of transaction with which it is associated or the time frame within which the image was captured. The ability to search such images by one or more of these parameters would greatly reduce the time necessary to locate desired images. In addition  
20 there exists a need for the selective deletion of images when available storage space approaches depletion. Such selective deletion may include eliminating image data associated with certain types of image events while selectively retaining other information.

There further exists a need for a system which can provide increased assurance of the authenticity and unaltered condition of an image. In some circumstances there may be concern that a captured image has been altered so that it is different from its original form. The ability to document that images are unaltered despite transfer from an image capture system to another system increases the evidentiary value of the captured image.

There further exists a need for an image capture system that can be used in connection with automated transaction machines as well as in other transaction or service environments. Such a system may record activities and transactions occurring within facilities at particular times to enable documentation of events that occur.

Thus there exists a need for a transaction record system which includes image capture capabilities that overcome the limitations associated with existing systems.

#### DISCLOSURE OF INVENTION

It is an object of the present invention to provide a transaction record system for an automated banking machine.

It is a further object of the present invention to provide a system for recording image data related to transactions conducted at an automated banking machine.

It is a further object of the present invention to provide a system for recording image and transaction data related to transactions conducted at an automated banking machine.

It is a further object of the present invention to provide a system for enabling access to image and transaction data related to transactions conducted at an automated banking machine remotely through a network.

It is a further object of the present invention to provide a system for accessing image and transaction data in response to events that occur at an automated banking machine.

It is a further object of the present invention to provide a system for obtaining image data and for taking actions in an appropriate programmed sequence in response to events at an  
5 automated banking machine.

It is a further object of the present invention to provide a system for obtaining image data and for taking actions in a sequence which can be programmed more readily.

It is a further object of the present invention to provide a system which achieves greater assurance of capturing useful image and transaction data related to transactions conducted at an  
10 automated banking machine.

It is a further object of the present invention to provide a system that provides selective remote notification of events and conditions occurring at an automated banking machine.

It is a further object of the present invention to provide a system that simplifies the recording, storage and analysis of transaction and image data generated at an automated banking  
15 machine.

It is a further object of the present invention to provide a system for imaging documents at an automated banking machine.

It is a further object of the present invention to provide a system that enables analysis of documents presented at an automated banking machine.

It is a further object of the present invention to provide a system for obtaining and storing  
20 image data related to servicing activities conducted at an automated banking machine.

It is a further object of the present invention to provide methods of recording, storing and analyzing image and transaction data produced in the operation of an automated banking machine.

5 It is a further object of the present invention to provide an image capture system that captures images in response to triggering events and which captures images in accordance with a programmed sequence of actions.

It is a further object of the present invention to provide an image capture system in which the triggering event is the occurrence of an image condition within a field of view of a camera.

10 It is a further object of the present invention to provide an image capture system in which images are captured in response to a triggering event which includes changes within a selected detection area within a field of view of a camera.

It is a further object of the present invention to provide an image capture system which captures images in response to a triggering event which includes the presence of a particular characteristic, object, facial feature or color within an image.

15 It is a further object of the present invention to provide an image capture system that can provide remote notification of a triggering event and to include with the notification an image associated with the event.

It is a further object of the present invention to provide an image capture system which provides for selective deletion of images by the type of event with which the image is associated.

20 It is a further object of the present invention to provide an image capture system in which images may be sorted and searched by parameters or combinations of parameters.

It is a further object of the present invention to provide an image capture system which provides for transferring images in a manner which provides enhanced assurance that the transferred images have not been altered.

Further objects of the present invention will be made apparent in the following Best  
5 Modes For Carrying Out Invention and the appended claims.

The foregoing objects are accomplished in one exemplary form of the present invention by a system which includes an automated banking machine. The automated banking machine carries out transactions by performing several transaction functions. At least one camera is positioned adjacent to the automated banking machine. The camera operates to produce camera  
10 signals which represent images within a field of view of the camera.

The system further preferably includes a computer in operative connection with a data store. The computer includes a server operating in connection with the computer. In some embodiments of the system the server may be resident and a part of the computer within the automated banking machine. In other embodiments the server may reside in a location adjacent  
15 to or disposed from the automated banking machine. The computer is in operative connection with the machine and the camera. The computer operates in accordance with programmed instructions to include image data corresponding to the camera signals in the data store. The image data is stored in response to the machine carrying out transaction functions.

The server is in connection with an electronic communications network. In some  
20 embodiments this may be a direct connection, local area network or an intranet. In other embodiments the network may be a telecommunications network, wide area network or the Internet. Alternatively the network could include a wireless network such as an RF network or

satellite network. A user terminal disposed from the automated banking machine is connected to the network. The user terminal may be connected directly to the network or may be connected through one or more intervening networks and servers. The user terminal includes a computer with a browser operating therein as well as an output device such as a screen or printer. The user terminal through the browser accesses the image data through the server. The user terminal operates to output the image data through its output device. The user terminal also is used to access transaction data related to transactions corresponding to image data stored in the data store associated with the server. The user terminal may be operated to more rapidly analyze and sort image and transaction data, as well as to conduct a more detailed analysis of image or transaction data.

Embodiments of the system also operate in accordance with sequences of instructions. The sequence instructions provide for a sequence of actions to be taken in response to certain conditions. For example if in the course of capturing image data, a camera adjacent to the ATM is unable to produce usable video, such as because it is covered or due to glare, the instructions in the sequence may cause the system to begin capturing image data from another nearby camera. Other sequence instructions may avoid recording the image data for selected transactions. Other sequence instructions may cause the recording of images associated with service activities. This may be done with cameras located in service areas such as behind an automated teller machine or within the automated teller machine itself. Selective motion detection and other hard and soft triggers may be used to initiate recording of images and/or other actions which are part of a sequence.

Alternative embodiments of the invention also provide messages through the network indicative of conditions or events occurring at the automated banking machine. Further embodiments of the system operate to manage available memory. This may include projecting when available memory will likely be depleted and sending a message which indicates such condition. Other embodiments may reconfigure available memory or may automatically delete selectively certain image data or off-load data in memory through the network to a remote storage location. Further alternative embodiments of the invention provide for imaging of documents deposited in the machine. Image and transaction data associated with the deposit of documents may be recovered. Analysis of document image data such as signature analysis may be conducted through the network remotely from document verification terminals which include data usable to verify the genuineness of deposited documents.

Alternative exemplary embodiments of the invention are used independent of an automated transaction machine to capture image data selectively in response to triggering events. Such triggering events operate to cause the system to execute sequences which may include the capture of additional images or to take other actions including the remote notification of persons electronically of the occurrence of triggering events. Such notifications may include or have attached thereto at least one image file corresponding to an image associated with the event for which notification is being given.

In certain exemplary embodiments the triggering events include certain image conditions. Image conditions may correspond to the blocking of a camera in a way that prevents the delivery of usable video. Alternatively image conditions may correspond to the detection of motion, colors, objects, facial features, clothing, body positions, or other characteristics or items within a

field of view of a camera. Exemplary embodiments of the invention enable a user to select one or more subsets of the field of view as a detection area and to sense for motion or other image conditions only within the detection area while ignoring image conditions outside the detection area. This facilitates the detection of desired events and avoids the use of available image storage in response to capturing images which are not of interest.

Exemplary embodiments of the invention also store image data and other data associated therewith so as to provide enhanced searchability of images. Embodiments of the invention enable searching through images selectively by one or more parameters. Such parameters may include the type of triggering event causing the image to be captured. Other exemplary parameters may include transaction types with which an image is associated, or time periods during which images are captured. Other parameters for the searching of images may include searching by color, object type, facial features or other characteristics. Such capabilities enable images to be identified, recalled and analyzed selectively, more quickly or in greater detail than is possible with existing systems.

Exemplary embodiments of the present invention also enable the transfer of images that have been captured in a manner that provides greater assurance that the images have not been subject to alteration. Such capability assures that the image has greater evidentiary value in the event that it is used to establish liability related to the occurrence of transactions or events.

#### BRIEF DESCRIPTION OF DRAWINGS

Figure 1 is a schematic view of an exemplary embodiment of a transaction record system of the invention used in connection with an automated banking machine.

Figure 2 is a schematic view of a control system for devices within an automated banking machine which incorporates a first embodiment of a transaction record system of the invention.

Figures 78 through 80 are charts showing the various functions performed by selection of icons in the exemplary control panel when particular image pages are being displayed.

Figures 81 through 83 are schematic views showing the operation of the icons included in the exemplary control panel screen in navigating through images which are presented to a user at a user terminal.

Figure 84 is a chart explaining variations in an icon used in connection with designating images for deposit into an image cart for purposes of downloading images as a group, and the functions associated with the icon.

Figure 85 is an exemplary embodiment of a screen presented at a user terminal for purposes of providing the user with greater image integrity assurance for downloaded images and a unique key or password for purposes of enabling the unlocking of such images.

#### BEST MODES FOR CARRYING OUT INVENTION

5 Referring now to the drawings and particularly to Figure 1 there is shown therein an exemplary embodiment of the present invention which operates as a transaction record system for an automated banking machine generally indicated 10. The system of this embodiment includes an automated banking machine 12 which in this example is an ATM. It should be understood that in other embodiments of the invention other types of automated banking  
10 machines may be used. ATM 12 includes a number of transaction function devices. These transaction function devices are associated with components of the machine such as a card reader 14 and a keypad 16. The card reader and keypad serve as input devices through which users can input instructions and information. It should be understood that as referred to herein the keypad includes function keys or touch screen inputs which may be used in other embodiments to input  
15 data into the machine.

ATM 12 further includes additional transaction function devices. Such transaction function devices may include a presenter schematically indicated 18 which operates to present cash or other documents of value to a customer. The presenter 18 in the embodiment shown is associated with a dispenser schematically indicated 20 (see Figure 2). The dispenser is operative  
20 to obtain sheets such as currency bills from within the machine and to deliver them to the presenter in the described embodiment. In alternative embodiments only a presenter or a dispenser may be used. The exemplary ATM 12 further includes a depository 22. The

depository 22 accepts deposits from customers. In the embodiment shown the depository is generally configured to accept cash and other instruments such as checks from a customer. It should be understood that in other embodiments other types of depositories which accept various types of items representative of value may be used.

5           The transaction record system of the described embodiment further includes a first camera 24. Camera 24 is positioned within or behind the fascia of the ATM or otherwise adjacent the ATM so as to have a field of view which generally includes the face of the user operating the ATM. A further camera 26 is positioned adjacent to the ATM and includes a field of view which includes a profile or other view of the user operating the ATM.

10           A further camera 28 in this exemplary system is shown positioned adjacent to the ATM with a field of view to observe a service area of the ATM. Camera 28 in the exemplary embodiment shown is directed to observe the back of the ATM and is usable for observing or detecting service activities. Camera 28 may be for example positioned within a vestibule or room which is accessed by service personnel for purposes of servicing the ATM. A further  
15 camera 30 shown schematically, is positioned adjacent the ATM and within the interior of the cabinet of the ATM. Camera 30 is shown having a field of view which is directed generally opposite to that of camera 28 and enables it to view areas which would normally include the face and hands of servicing personnel. Camera 30 preferably operates when a service door 32 is open and a servicer is accessing the interior of the machine. This enables capturing image data related  
20 to persons servicing or accessing the interior of the machine.

          In the embodiment shown each of the cameras 24, 26, 28, 30 provides camera signals which are analog signals representative of what is observed within the field of view of the

respective camera. It should be understood that the camera configuration shown in Figure 1 is exemplary and other configurations of cameras, or greater or lesser numbers of cameras, may be used in connection with embodiments of the invention. It should further be understood that embodiments of the invention may include digital cameras or other types of devices from which  
5 images may be reproduced.

Figure 2 shows a schematic view of a first hardware configuration of a transaction record system of the invention. The automated banking machine 12 includes the transaction function devices 14, 16, 18, 20, 22 which communicate through and are operated responsive to signals passed through device interfaces 34. The device interfaces communicate with the transaction  
10 function devices on an interface bus 36. The messages which control operation of the various transaction function devices are communicated through the interface bus. A computer which is referred to as a terminal controller 38 operates the ATM by sending messages to the device interfaces to control the transaction function devices.

In the embodiment shown in Figure 2 an image recorder device 40 is shown connected to  
15 the interface bus 36. Image recorder device 40 in the embodiment shown is a separate hardware component from the automated banking machine. Image recorder device 40 includes a computer which includes a server operating therein, and further includes a data store schematically indicated 42. The data store holds programmed instructions. The data store also holds data representative of image data, transaction data and other data as later described. It should be  
20 understood that although a data store within the image recorder device is described in the exemplary embodiment, reference to a data store herein encompasses either a single data store or a plurality of connected data stores from which data may be recovered.

Image recorder 40 receives the analog signals from the connected cameras 24, 26, 28 and 30 as shown. It should be understood that embodiments of the invention may include devices which in addition to image data, acquire sound data, infrared signal data and other types of data which can be sensed by sensing devices, stored, recovered and analyzed by the system. Image recorder device 40 further includes inputs which are schematically represented as hard and soft triggers. Hard triggers, examples of which are hereinafter described, are signals from “hard devices” such as sensors. Such devices can generally sense actions or conditions directly such as that a service door on the ATM or to a service area has been opened. The image recorder device also receives soft triggers which may include signals representative of conditions or instructions which are being sent as signals to other devices. Such soft triggers may further include the signals on the interface bus 36 in the embodiment shown or timing signals or other signals usable to operate the image recorder responsive to programmed instructions, time parameters or other conditions or signals.

Soft triggers may also include timing functions. In some embodiments the image recorder may monitor other types of transaction messages and may operate in response thereto. Such alternatives may include for example, systems where the image recorder device 40 is not connected to the bus with the transaction function devices, but instead monitors transaction messages being sent between an automated banking machine or other device and a remote computer, and extracts information concerning the operation of transaction function devices from such messages. Other configurations and operational capabilities of the image recorder device will be apparent to those skilled in the art from the description herein.

Image recorder 40 in the exemplary embodiment is in communication with an electronic communications network schematically indicated 44. Network 44 in the described embodiment may be a local area network such as an intranet or may be a wide area network such as the Internet. In the embodiment shown network 44 is a network that communicates messages in protocols such as TCP/IP. The network is used to further communicate HTTP messages including records such as HTML, XML and other markup language documents. Of course in other embodiments of the invention other communications methods may be used.

The image recorder device 40 includes a computer operating at least one server. The server is connected to the network and has at least one uniform resource locator (URL) or other system address. This enables the server to be accessed by other terminals connected to the network as well as to selectively deliver messages to connected terminals. It should be understood that network 44 may be connected through intermediate servers to other networks. This enables the image recorder device 40 to communicate with other types of remote terminals including terminals connected to wireless interfaces such as pagers and cellular phones. If network 44 is an intranet, intermediate servers which operate as a firewall may be included in the system. Access to the Internet enables the communication of messages to terminals located anywhere in the world. Such communications capability may be valuable in embodiments of the invention for purposes of image and transaction data recovery and analysis, and for purposes of sending messages to individuals to be notified of conditions which exist at the automated banking machine.

A plurality of terminals 46 are shown connected to the network 44. Terminals 46 may include a user terminal for purposes of programming parameters into the data store 42 of image

recorder device 40. Alternatively terminals 46 may include user terminals which may be used to analyze and recover image data and transaction data from the image recorder device. Alternative terminals 46 may include data stores for storing image and transaction data which is downloaded from the image recorder device for purposes of storage as later described herein. Alternative  
5 terminals 46 may include document verification terminals for verifying the authenticity of documents, identifying user data or for carrying out other functions described herein. Typically terminals 46 include computers including a browser component schematically indicated 48. The browser communicates with the server in the image recorder device to access the image data. Such a browser component may be commercial browsers such as Netscape Navigator™,  
10 Microsoft Internet Explorer™ or other types of browsers. Terminals 46 also include other software and hardware components schematically indicated 50 suitable for processing image data, transaction data and other data that may be obtained by accessing the server in the image recorder device 40.

An exemplary terminal indicated 52 is shown in greater detail in Figure 2. Exemplary  
15 terminal 52 may be a user terminal, document verification terminal, data storage terminal, data analysis terminal or other type of terminal for inputting instructions or analyzing data available in the system. Terminal 52 in the exemplary embodiment includes a computer schematically indicated 54 which includes an associated data store schematically indicated 56. As with other data stores described herein, data store 56 may be a single data store or a number of operatively  
20 connected data stores. Terminal 52 further includes in operative connection with the computer 54, input devices 58 and 60 which include a keyboard and mouse respectively in the embodiment shown. Of course in other embodiments other types of input devices may be used. Terminal 52

further includes output devices. The output devices in the embodiment shown include a monitor with a display 62 and a printer device 64. Of course in other types of terminals other types of output devices may be used. The terminal 52 includes a computer with a browser component as previously described. The browser in the terminal communicates with the server in the image recorder device 40 through the network 44 for purposes of carrying out the functions later described in detail herein. Terminal 52 may also have a server operating therein as well as other software components.

The operation of exemplary embodiments of the invention are further described with regard to the interaction of logical components of the system described in connection with Figures 3 through 9. It should be understood that the logical components are generally combinations of software and hardware used in carrying out the described functions. As shown in Figure 3 the input signals from the cameras, microphones or other input devices are input to the device switching controller component 66. The device switching controller component in embodiments of the invention may include several components. The switching controller delivers signals, which in the described exemplary embodiment are analog signals, selectively in response to a record acquisition control component 68. The record acquisition 68 component receives hard and soft trigger signals including signals which control or otherwise indicate the operation of the transaction function devices in the automated banking machine or other signals which are used as an indicator to initiate a sequence of actions. The record acquisition component executes the instructions which indicate which image signals are desirable to process and record in response to the trigger signals. The record acquisition component further includes or works in connection with stored instructions, which are operative to detect conditions such as

loss of usable video from a camera or other input device, and to begin acquisition of data from other devices in response thereto.

The exemplary record acquisition component also operates in connection with stored programmed instructions to sense motion in the field of view of selected cameras or other input devices. As later described such instructions may include limiting the area of analysis to one or more selected detection areas within a field of view, and disregarding other areas. The record acquisition component may further process and pass off other data such as transaction data related to the operation of an automated banking machine for storage in correlated relation with image data. In some embodiments of the invention transaction and other numerical type data is selectively captured and stored in file records that are maintained separately from image data. Such transaction data may be correlated with image data at the time (which also indicates a date or other period of time) associated with the activity which is recorded for both image and transaction data. However in other embodiments of the invention other methods for such correlation may be used.

In this exemplary embodiment the record acquisition component in accordance with programmed instructions further controls encryption techniques used in connection with image data, as well as data compression techniques which are used for storing images. The record acquisition component may further operate to store data and control other activities such as the sending of e-mail or other messages in response to the occurrence of certain conditions.

The record acquisition component 68 in this embodiment operates to send one or more camera signals to a frame grabber component 70. The frame grabber component is operative to generate digital image data corresponding to the analog camera signals which are passed to the

frame grabber by the record acquisition component. Of course in embodiments where digital cameras are used the image data does not need to be digitized by a separate component. The image data from the frame grabber in this exemplary embodiment is passed to an encryption/authenticate component 72 which may be operated to include authenticating information within the image data. Such authentication data may include digital signatures, digital watermarks or other data which can be used to verify that an image has not been tampered with since it was acquired. In addition component 72 may operate to encrypt image data so as to minimize the risk of such data being accessed by unauthorized persons. In alternative forms of the invention such an encryption component may not be used.

A data compression component 74 may operate to compress the image data to minimize the amount of storage required for holding it. Such data compression may be performed through a number of different standard or nonstandard schemes. The degree of data compression may be selectively controlled. In this exemplary embodiment of the invention, the degree of data compression is programmable and may be changed through real time inputs or may be programmably controlled to change the degree of data compression. For example instructions stored in connection with the record acquisition component 68 may dictate that in response to certain events which are detected through hard or soft triggers, high quality image acquisition is required. In such cases data compression may not be used or a lesser degree of data compression may be used, to increase the quality of the images. Of course in such circumstances the record acquisition component may also increase the frequency at which images are captured from various input devices. In some instances, the image capture frequency may be increased to the extent that clips of generally visually continuous images are captured and stored.

After the image data is compressed it is transferred to a RAM cache store component 76.

The RAM cache store stores the image and transaction data (and other system data that the record acquisition component may dictate be stored for a period of time). It should be understood that embodiments of the invention may operate to analyze cache store data for purposes of detecting and analyzing image and transaction data and for taking action in response thereto in accordance with programmed instructions. In some embodiments of the invention the record acquisition control component 68 operates to place images in storage from all cameras on a regular or nonregular periodic basis. These records initially do not correspond to any triggering event. However, embodiments of the invention may operate in response to programmed instructions when a triggering event occurs to associate one or more images immediately proceeding the triggering event to be associated with the images captured in response to the triggering event. This enables embodiments of the system to capture and retain those images of conditions which existed prior to an event. Such images may often provide valuable information concerning activities that preceded and/or caused the event.

In this exemplary embodiment, from the RAM cache store, image and transaction data is transferred in the system to a disk cache store 78. From the disk cache store 78, image and transaction data is subsequently transferred to an archive store component 80. The archive store component may in some embodiments be a permanent or temporary storage media such as a removable storage media as hereinafter described. Alternatively the archive store disk may be a CD-R/W type device or similar storage media which may provide temporary or permanent non-modifiable storage of image and/or transaction data. Alternatively various types of storage devices that may be off loaded or overwritten may be used.

The archive store component operates in connection with a file management component 82. The file management component 82 operates in accordance with programmed instructions to perform various operations. The file management component works in connection with other components to provide access to stored image and transaction data. The file management component also enables control of available memory to facilitate storage of data and minimize the risk that transaction and image data will be lost.

As represented in Figure 4 the file management component 82 may work in connection with interface 84 to provide access through an intranet schematically indicated 86. As previously mentioned, terminals connected to the intranet may be used to access the stored data. A server 88 which operates as a firewall may be used to provide selective access to the intranet and to provide access to other networks. Such other connected networks may include a wide area network such as the Internet.

Alternatively an interface 90 may be used to provide access directly to the Internet schematically indicated 92. Appropriate controls may be used to minimize the risk of unauthorized access such as passwords and/or public key encryption. Digital signatures, session keys and the like may also be used to limit access to authorized persons.

An interface 94 may be provided to telephone communications networks. This may be accomplished through a dial up connection or a cellular connection. Such an interface may be provided for purposes of sending messages such as pager, fax or voice mail communications selectively to remote users or facilities.

An interface 96 to a lease line or other dedicated communications line may be provided for purposes of providing for both messaging and data communication. Of course in other

embodiments other types of communications interfaces for communicating messages and for providing access to image and transaction data may be used. The particular configuration used will depend on the needs of the system and the capabilities of the remote communications method.

5           As discussed previously, the file management component 82 may be in operative connection with a fixed local storage component such as a data store schematically indicated 98. The local data store 98 may in the embodiments of the invention include database software operating in a data store in connection with a processor or computer in the automated banking machine. Alternatively the database may operate on the computer within the image recorder  
10       device 40 or in other computers operatively connected with the image recorder device.

          In embodiments of the invention, the image recorder device 40 or a connected device may include an image and transaction data recorder schematically indicated 100 in Figure 4. The transaction data recorder operates to record image and/or transaction, or other data on a removable storage medium 102, such as a CD-R/W or other storage device. Such a removable  
15       storage device may include a permanent storage media which requires periodic replacement, but which is not subject to later possible modification as is the case with erasable storage. Such removable storage media may work in conjunction with other local storage or remote storage. Operating under the control of the file management component 82, this feature may in embodiments of the invention enable storage of data in other data stores which accepts overflow  
20       data on a temporary basis when the removable storage medium has become filled. When the removable storage media is changed, the recorded data in temporary storage in the other data store is transferred thereto. Alternatively, the file management control component may operate to

periodically erase images and data as storage space is needed. This may be done selectively based on the age of the image, the nature of the event causing image capture or other parameters. Of course other approaches may be used.

As previously discussed, the file management component 82 may alternatively operate to cause the computer within the image recorder device to off-load image and transaction data. The off-loading of data may be made to remote storage devices schematically indicated 104 associated with connected terminal devices to which data may be sent through the network 44. Of course in alternative embodiments of the invention other approaches and techniques may be used.

Figures 5 through 9 are schematic views which represent the operation of components comprising executable instructions in exemplary embodiments of the system. These components are preferably software components which operate in connection with the record acquisition component 68 and the device switching control component 66. In Figure 5 a logic flow associated with motion detection is shown. The inputs from the cameras or the other input devices are processed by a detection area definition component 106. The definition component contains data and instructions representative of one or more detection areas in the field of view of particular cameras that are to be analyzed and/or disregarded for purposes of detecting motion.

In some systems motion may be occurring fairly frequently within a field of view of the camera, but such motion is not of interest and it is desirable to not capture image data in response to such motion. For example when a camera is located in the security area from which the serviceable components of the banking machine are accessed, motion may normally occur within a portion of the field of view of the camera while in other portions of the field of view motion

only occurs when the machine is being accessed. A camera located in an ATM vestibule may have a window within its field of view. Activity occurring outside the window may not be of interest and optimally should not result in image data being recorded. Motion detected through the window is disregarded responsive programmed instructions in the motion detection component which excludes from the analysis movement detected within the window portion of the field of view.

A camera positioned in the interior of an ATM housing may detect motion even when the service door of the machine is not open. This may occur due to flashing LEDs or other indicators within the interior of the machine. The detection area definition component 106 may define detection areas that exclude such sources of light or motion from the motion detection analysis. In certain systems vibration or other regular movement may cause certain fixed objects to appear to move relative to a camera's field of view. The detection area definition component may be used to exclude from the analysis images of known objects within an area of normal movement. The detection area definition component establishes those areas of the field of view of each camera in which changes in the image indicative of motion are to be analyzed and/or those areas in which changes indicative of motion are not to be analyzed. It should be understood that the definition component may in alternative embodiments apply to other sensing devices such as infrared sensors or other sensor types which have a field of view for sensing regions in which activities are to be disregarded. It should also be understood that the definition component 106 may also be set such that all regions in a field of view which make up an image are analyzed for purposes of motion detection.

The detection area definition component may preferably be configured remotely by authorized users at user terminals connected to the network. This is preferably accomplished by inputs which divide portions of the field of view of each camera into one or more areas where detected motion is of interest and not of interest. Such areas are preferably designated graphically on the output screen of a user terminal and are readily changed by inputs from authorized users.

The detection area definition component communicates with a motion detection component 108. The motion detection component includes instructions which operate to compare sequential images obtained from the camera inputs. In one exemplary embodiment this is done by comparing intensities or color of corresponding pixels in sequential images. The sequential images are analyzed at periods fairly close in time. Changes in intensity or color of corresponding pixels of greater than a threshold amount are counted or otherwise mathematically analyzed. Changes above the selected threshold for at least a selected number of pixels in the entire image or selected detection area(s) of the image, indicate a substantial enough change such that motion is considered to have been detected. When motion is detected in an area of interest the motion detection component signals a device within control component 110 which operates the device switching controller 66 and the record acquisition component 68 to acquire image data from the camera at which motion has been detected. The system may also move into more permanent storage image data captured prior to the triggering event depending on its programming.

It should be understood that the motion detection feature is only used to capture images from those cameras for which the system has been programmed to acquire image data based on

motion detection. In the exemplary system shown, this is generally in the secure areas within the machine or an exterior area adjacent the area where a servicer performs operations. If the system is not programmed to acquire image data based on motion detection from a particular camera, motion within the field of view of that camera will not result in the more permanent storage of image data.

As previously discussed alternative forms of the invention may operate to capture images on a generally continuous periodic basis. Such images may be temporarily stored in a queue or other memory and erased after a period of time. Systems of the invention may be programmed such that motion detection may be determined based on comparisons of pixels which make up these digitized images. The detection of motion may also cause the system to operate in accordance with programmed instructions to retain one or more images from the queue that preceded image in which motion was detected, and to store these prior images in correlated relation with the images captured in response to the triggering event. This feature enables an operator to review the conditions in the field of view of the camera prior to the triggering event. Such information will often prove useful in determining conditions or activities which led up to the triggering event.

The memory configuration of the described embodiment provides advantages in that the system is enabled to capture image and transaction data while delivering image and transaction data from storage. As a result unlike prior art systems, the capture of image data does not have to be suspended while images are recovered or downloaded from the system. Further, the configuration of the system enables capturing image data from a number of sources virtually simultaneously. This solves a problem associated with certain prior systems which when

configured to detect motion, operate to record only from a particular camera where motion has been detected. Other image data cannot be captured while image data is being captured from the camera where motion was detected. This presents opportunities for compromise of such systems by creating a diversion at a first camera and then carrying out improper activities within the field of view of another camera. The preferred form of the invention does not suffer from this deficiency as image data may be captured in a plurality of cameras virtually simultaneously, and triggering the capture of images based on detection of motion at one camera does not suspend image capture from other cameras. The system can also be delivering image and transaction data to a remote location while concurrently capturing such data from a plurality of sources.

The motion detection feature may operate in connection with an analysis component 112. The analysis component 112 may be used in various embodiments of the invention to determine various information of interest. This may include for example to measure how long it takes a particular servicer to perform particular service functions within a machine or within a service access area. Alternatively, the analysis component may be used to determine how long customers remain watching an output device on the banking machine before, during or after a transaction is completed. This may be used to provide information concerning the degree of interest that a particular customer or customers in general may have in a particular type of promotional presentation that is made at the automated banking machine or other output device. Such information may be recorded in connection with the data store and later used for further analysis. Such analysis may include in the case of the servicer, comparing performance of service providers or determining the relative ease of servicing of various types of machines or components. It can also be used to determine if, or for how long, a servicer had activity related

to a component in the machine. In the case of customers and users, the analysis data may be used for targeting promotional type information to users in the future as well as for evaluating the effectiveness of marketing type activities presented through the automated banking machine.

The functions performed by the analysis component 112 on the captured data will depend on the particular nature of the data to be analyzed, but such analysis may be facilitated by the availability of image and transaction data which is stored in correlated relation in the data store with the movement analysis data so that the validity of any conclusions made can be verified.

Figure 6 schematically represents a further aspect of the operation of embodiments of the present invention. Figure 6 represents an example of how the system operates to capture image and transaction data in response to hard trigger inputs. Such hard trigger inputs generally correspond to sensors which sense conditions or other activities adjacent to the machine. As schematically represented in Figure 6, a sensor 114 provides an input signal which is received by a hard trigger logic component 116. The hard trigger logic component is operative to determine the nature of the input and to communicate with a timing/sequence logic component 118 which controls what occurs in response to the particular input corresponding to a triggering event.

For example the sensor 114 may be representative of a sensor which senses when a service door on an automated banking machine is opened. The executable instructions programmed in connection with the system include instructions which comprise a sequence which controls what is to happen when this event is sensed. The timing/sequence logic component 118 will generally include information that may be time dependent, and/or a sequence of actions which are to occur. The sequence may include for example having image data captured generally continuously from particular designated cameras while the door is open. The

sequence may further include sending one or more e-mail messages to particular e-mail addresses through the network so that individuals are notified that the machine has been accessed. As different entities may have responsibility for servicing machines depending on the date of the week or time of day, the routing of such messages may be time dependent and the programmed instructions may operate to send the messages to different addresses depending on the time that the event occurs. Such messages may include electronic mail messages which have one or more of the images captured included therewith.

The timing/sequence logic component 118 works in connection with a device switching control component 120. The device switching component 120 is operative to work in conjunction with the device switching controller 66 and the record acquisition control 68 to acquire image data from the selected cameras through the frame grabber. The device switching control component 120 may also be programmed in other embodiments to take other actions such as to operate or interface with alarm systems, automatic locking systems or other types of devices. In addition as previously described the timing/sequence logic component may also operate to temporarily acquire images from various cameras or other image capture devices on a periodic basis. The programmed instructions associated with the particular triggering event may include storing on a more permanent basis one or more images captured prior to the triggering event. These images may then be stored in correlated relation in the data store with the images related to the event. Such information enables an analysis to be made as the causes or events preceding the triggering event.

Figure 7 is a schematic view of the operation of the system to acquire image and transaction data in response to soft trigger inputs. Such soft trigger inputs may include for

example messages to or from transaction function devices on the interface bus within an automated banking machine. Alternatively such soft trigger inputs may include transaction messages transmitted between an automated banking machine and a host. Other types of soft trigger inputs may include receipt of other electronic messages either alone or in relation to other messages, so as to indicate a condition which requires image or transaction data acquisition. Other types of soft trigger events may be initiated in response to timing functions which operate based on programmed instructions and the current time, or which are timed from other events.

The soft trigger logic component 122 is operative to receive the soft trigger inputs and to analyze the nature of the conditions represented by the inputs received. For example the soft trigger logic component may determine based on software instructions stored in memory that particular signals on a bus or line being monitored represent the input of a customer card to a card reader and the account number associated with that card. In certain embodiments of the invention such account data is captured as part of the transaction record data and the input of such a card to the card reader is used as a trigger to capture image data so that there is a record of the user that input the card. Likewise messages indicative of the presentation of cash to a customer by a presenter may be detected and used as a further triggering event to capture image data.

In certain exemplary forms of the invention a series or set of images is captured in connection with a transaction carried out by a user in an automated banking machine. Such images in the set are preferably captured in response to the operation transaction function devices on the machine. Such images are stored and may be recovered and displayed together for later analysis. The storage of multiple images in a set related to customer transactions increases the

likelihood that suitable images of the user and/or background will be acquired which may prove useful later if such images require analysis. In addition, the fact that account data and/or other transaction data is captured in connection with the image data and can be correlated therewith, enables searching the transaction data to recover the image data associated therewith. For

5 example, because the transaction data commonly captured may include the account number as well as the user name encoded on the card, the transaction data may be searched using these parameters. This enables readily identifying transactions corresponding to these parameters and retrieval of the image data associated therewith. This greatly reduces the time to locate pertinent images compared to other systems. In addition, other types of sorting parameters may be used to  
10 recover images. These include for example, time periods during which transactions were conducted, amounts of deposits, amounts of withdrawals or other transaction parameters. Any of these transaction parameters that are stored in connection with or which may be correlated to image data may be used to selectively identify and recover images. Of course in other embodiments other approaches to the capture of image data, transaction data and other types of  
15 soft trigger logic may be used.

Soft trigger logic component 122 operates in connection with a timing/sequence logic component 124. The timing/sequence logic component is operative responsive to programmed instructions input by a user during setup of the system. The timing/sequence logic component operates to capture image and transaction data selectively from various cameras and/or  
20 transaction function devices depending on events that are occurring and/or the date and time of such events. For example if particular transactions are occurring the timing/sequence logic component may take special actions different or in addition to those taken with regard to other

actions. An example may be when a customer seeks to deposit more than a certain amount of funds in the machine or seeks to cash or obtain value for an instrument. The timing/sequence logic component may capture more frequent images or images from additional cameras during the transaction. Another example may be in the case of a reportedly stolen card. If the soft  
5 trigger logic identifies the input card as stolen, the logic component may operate to not only acquire additional image data, but also to send messages through the system or through other communications channels to police or other authorities.

A further example may be used in connection with a banking machine which includes check accepting or other document accepting devices where the authenticity of the inserted  
10 document may require verification. The timing/sequence component may work in connection with an imaging device within the automated banking machine to capture an image of indicia on the inserted document, and to transmit an image of the document while the transaction is ongoing to a verification terminal in the network. Such a document may be viewed at such a terminal and/or electronically analyzed to compare the image of the document to verification information  
15 such as a handwriting or signature database for purposes of determining authenticity. The destination where such messages are sent may be varied depending on the nature and/or amount of the document, the time of day and other parameters depending on the instructions associated with the timing/sequence logic component 124.

Other exemplary applications of timing/logic sequence include minimizing the use of  
20 available image data storage by reducing or eliminating the amount of image data acquired related to certain transactions. For example the timing/logic sequence may include instructions to capture fewer or no image data related to transactions conducted that are of certain types. This

may be appropriate for example in the case of an account balance inquiry. Likewise the instructions may provide that a dispense of cash below a particular amount, such as for example \$100, may not result in the acquisition of image data. Likewise, certain deposit transactions for certain customers within certain limits may not require the capture of image data, or may have the system capture a lesser number of images than is captured in connection with other transactions.

The timing/sequence logic component 124 may operate in connection with instructions that capture additional image data in connection with certain transactions by certain individuals. Additional image or transaction data may be captured based on selected time of day, or a combination of time and day, amount or the nature of the individual customer. Various schemes for using customer profile data, time of day data and other information accessible through the network may be used in combination with the soft trigger inputs to selectively control the image and transaction data capture capabilities, and the message sending and device control capabilities of the system in response to selected circumstances that may arise in the operation of the automated banking machine.

A device switching control component 126 operates responsive to the timing/sequence logic component to capture image data during the transaction. The device switching control component further operates to capture transaction data in connection with the transaction. This may include for example time and date data, account number data, amount data, transaction number data, user name data, machine location data and other data which can be derived from the soft trigger inputs or other information available to the machine. Such data may also include multiple items of similar data such as time data. This may be desirable for example when the

ATM has an internal clock and the image storing device has its own associated system clock which may not be perfectly synchronized with the ATM clock. Capturing time data corresponding to both clocks may avoid confusion. Alternatively, programming may be provided for automatic clock synchronization and/or for obtaining time data or setting signals from another source.

In exemplary embodiments of the invention, the nature of the related data analysis can be set by the user during setup of the system. This is done through a user terminal and is preferably accomplished by selecting options in a setup window such as shown in Figure 25. The related data analysis and storage component 128 operates to capture and store the selected data. The data analysis and storage component is further operative to store the related transaction and other data in correlated relation with the image data. In certain embodiments of the invention such correlation is provided by storing data representative of the time and date associated with the image data and transaction data. In other embodiments other approaches to correlate the image and transaction data may be used.

In alternative forms of the invention the data storage and analysis component 128 may also include instructions for analysis of received data such as to provide statistical analysis related to use of the machine. Such data may be used in connection with developing a historical use pattern for the machine which may be used in connection with the memory allocation activities performed by embodiments of the system as later discussed herein.

Figure 8 is a schematic view of the logic flow associated with operation of embodiments of the invention where a lack of usable video information is detected with a camera that is to be operated in the course of a transaction. It should be understood that the lack of a usable video

logic may operate in connection with the motion detection logic, hard trigger logic or soft trigger logic previously described.

A lack of usable video detection component 130 operates in response to executable instructions to determine if a camera that is or may need to be operated is not providing suitable image data. This is done in preferred embodiments by comparing pixel data from the areas of the image that are indicated to be of interest by the detection area definition component 106 or from the entire field of view. The lack of usable video component 130 determines if pixels which comprise an image are generally all above or all below certain intensity or color levels and/or are lacking in contrast across the image so as to not provide a suitable image. The logic may check for example if generally all pixels are indicated as dark, which may suggest that a camera is being blocked or a lens has been spray painted so as to obscure the camera. Likewise the logic may check to determine if the pixels are generally all above a certain intensity value which may indicate that a glare condition created by reflected sunlight or a light operated by a person is obscuring a camera. The lack of usable video components may also operate based on detecting a rapid, large change in the field of view, or such a large change followed by an extended period without any change. A lack of usable video may also be based on detection of certain relatively unchanging high contrast images or sensing an unchanging image in a selected portion of a field of view. The lack of usable video component 130 may also be operative to detect that the camera signals have been interrupted. Various approaches may be taken to making a determination that there is a lack of usable video.

A timing sequence logic component 132 operates responsive to component 130 to take action in response to the condition. The action is taken in accordance with a programmed

sequence which is set up by a user and stored in a data store. The sequence may include for example responding to a lack of usable video by capturing image data from additional cameras. For example if in Figure 1 camera 24 is unable to provide usable video, image data may be captured from camera 26. The programming of the system may also operate in response to  
5 detecting a lack of usable video event to store in connection with the event one or more prior images that had been obtained and stored temporarily from the camera which is considered to be no longer providing usable video. Such images may be useful in determining the cause of the loss of usable video and/or the identities of persons which may have caused the loss of video.

In some exemplary embodiments the timing sequence logic component in response to the  
10 lack of usable video may cause the server component to generate a message to selected addresses in the network to indicate the nature of the condition. Such messages may include therewith one or more images. Likewise the timing sequence component may formulate messages to service entities responsible for repairing the system to indicate that there is a problem. In alternative forms of the invention the timing sequence component 132 may operate to perform activities  
15 through additional interfaces or computers such as turning on alarms, actuating additional lighting, contacting police authorities and/or disabling the automated banking machine. Such activities may be performed depending on the setup of the system as programmed by user.

The timing sequence logic component 132 operates in connection with a device switching control component 134. The device switching control component operates to capture image data  
20 responsive to programmed instructions and may also interface with other devices and systems to carry out functions determined by the timing sequence logic.

Figure 9 shows an alternative logic flow used in connection with embodiments of the invention in which features of a user are used to identify and/or authenticate the user or actions carried out thereby. The logic flow represented in Figure 9 includes an identification data acquisition component schematically represented 136. The identification data acquisition component in an exemplary embodiment operates to acquire data with a camera concerning a physical feature of the user. For example camera 24 may be used to acquire camera signals corresponding to a face of the user. An identification processing component 138 is used to compare the image data acquired to image data corresponding to a set of authorized users. Such authorized user data may be stored in a data store. As schematically indicated this data store may be within the automated banking machine or may be accessible through a network. Such identification processing may process not only user image data but also other data such as data from an object provided by a user, voice data, iris scan data, retina scan data or other data that can be used to indicate that a transaction is authorized.

If the identification processing component 138 is unable to identify the user then such information is provided to a machine control interface component 140. The interface component prevents operation of the machine but operates the system to capture image data related to the person who was unable to operate the machine. Alternatively if the user is identified as an authorized user by component 138, the machine control interface may authorize further operation of the machine, or may authorize such further operation if other indicia such as voice, numeric or other inputs correspond to the authorized user. Again the machine control interface component will operate to acquire image data concerning the authorized user. A data analysis storage component 142 operates to store data related to the transactions conducted by the authorized user

and is operative to store transaction data in the data store. This may include the various types of transactions conducted by the user and may further include storing in correlated relation with the user data, data representative of instruments deposited by such a user, instruments produced for such an authorized user or other information related to the user's transaction which is stored for later recovery. The nature of the transaction information captured will depend on the nature of the automated banking machine and the image and transaction data captured in connection therewith.

The capture of images from the various cameras on a continuing basis in embodiments of the system may also be used for other purposes. For example, the facial features of criminals, missing persons or other individuals of interest may be stored in connection with the data store. The system may operate so that content of images captured on a continuing basis from cameras, or alternatively images captured in response to triggering events, are analyzed so that the facial features of persons in images are compared to images stored in the data store. Responsive to finding a match the system may operate in response to programmed instructions to trigger a sequence which may include capturing additional images, sounding alarms or sending messages electronically to selected individuals. Such messages may include therewith the captured images as well as information concerning the person who was indicated to be recognized. Such facial recognition may be carried out for example in embodiments of the invention using software such as Face-It™ software which is commercially available from Lernout & Hauspie. Of course in other embodiments, other components and approaches to recognizing persons and images may be used.

In addition, because embodiments of the invention include image data stored in response to transactions and other triggering events, the stored data may be retrieved using the parameter of facial features or a particular individual's appearance. This may be done for example to identify instances where a particular service person has worked on a particular machine.

5 Alternatively transaction data may be reviewed to determine instances where a particular individual may have used the debit or credit cards of another person in conducting transactions. Numerous uses of searching through the image data using such parameters may be used.

Alternatively or in addition, the image data received by the system may be analyzed on a real time or periodic basis for the presence of other features in images. For example, images  
10 captured from a camera adjacent to an automated banking machine may be analyzed for the presence of certain objects which appear in the field of view of the camera. Such objects may include for example certain types of criminal tools used to attack the automated banking machine. Alternatively, objects which may be recognized may include certain types of weapons or other objects. Various body positions such as a person raising their arms or lying down might  
15 also be recognized. In response to a captured image having the image condition of including an object or characteristic which corresponds to one which is recognized by the system responsive to stored logic, appropriate responsive actions may be taken. Again, such actions may include sounding alarms, shutting down the automated banking machine and/or sending messages including messages which include images to programmed addresses or devices. Embodiments of  
20 the invention may operate in conjunction with or as part of a system as described in allowed U.S. Patent Application Serial No. 08/813,511 which is owned by the assignee of the present invention and the disclosure of which is incorporated herein by reference as if fully rewritten

herein. The identification of particular objects or features in the field of view of a camera may be operative to cause the dispatch of messages through one or more types of message media to predetermined recipients of such information. The dispatch of messages may include synthetic voice messages dispatched by phone or similar media, paging, radio messages or other types of messages. In addition, the responses to such messages may be monitored and tracked in accordance with programmed parameters to assure an appropriate response occurs.

A further advantage of embodiments of the present invention is that the stored image data is capable of being searched for other visual conditions or appearance features. For example, stored image data may be searched to uncover images which were stored of users with certain facial characteristics. Such characteristics may include features that may be recalled by another person of a potential witness to an activity which occurred in the area where the image capture system is operating. Such image capture capability enables images to be sorted to look for persons with features such as certain hair color, facial hair, skin color, tattoos, earrings, jewelry, or glasses as well as for certain types or colors of apparel. This may include for example hats, ski masks, bandanas, ties and jackets. The ability of the present invention to sort through image data and to recover images based on one parameter or a combination of parameters enables the recovery of images that using prior systems would require considerably greater time and effort. As can be appreciated from the foregoing description, embodiments of the invention provide many uses and advantages compared to prior art systems.

Figure 10 is a schematic view of an alternative form of the transaction record system of the present invention generally indicated 144. System 144 includes an automated banking machine which in the exemplary system is an automated teller machine schematically designated

146. Automated teller machine 146 is similar to the ATM described in the previous embodiments in terms of its outward appearance and configuration. However the computer and software architecture of ATM 146 differs.

ATM 146 includes a plurality of transaction function devices 148. The transaction function devices include devices which can be used to carry out transaction functions with the machine. These are similar to the transaction function devices of the previous embodiment. The transaction function devices generally include input devices such as a card reader, keypad, touch screen and/or function keys. The transaction function devices may also include devices for dispensing sheets and currency such as a bill dispenser and bill presenter. The transaction function devices may also include a depository, printing devices for printing transaction receipts, printing transaction records and other documents. The transaction function devices may also include a number of other devices.

The transaction function devices are operative in response to a device manager/interface component 150. The device manager interface component may be comprised of applets, programs or other applications written in a language such as JAVA by Sun Microsystems or Active X by Microsoft. Component 150 preferably includes data and instructions which represent operational relationships among the devices, and such data and instructions are schematically represented by a data store in connection with component 150.

The device manager/interface component 150 preferably operates the devices in response to HTTP format messages which are delivered by a device server 152. The device server 152 similarly includes a plurality of applets or other programs which operate responsive to messages received by the device server. The device server contains the instructions which generally

operate to control, coordinate and limit the operation of the transaction function devices within the ATM.

ATM 146 further includes a document handling portion 154. Document handling portion 154 is operative to process HTML documents and HTTP messages which the document handling portion selectively accesses. The document handling portion 154 includes a browser for selectively processing HTML documents or other documents. The documents accessed by the browser may include therein instructions such as JAVA script which are processed by the browser and which are operative to cause a computer to output messages through an output device such as a screen display of the ATM. The document handling portion 154 of this example further includes a server device that is operative to output messages to the other components of the machine as well as to a network 156 to which the machine is connected. The document handling portion 154 may access HTML or other documents through a bank server 158 or other servers which are connected to the network 156. The bank server 158 may also send and receive messages from the device server 152 and other components of the machine. As shown schematically, the bank server 158 is in operative connection with a back office processing system 160. The back office processing system is operative to maintain data records and account information, as well as to provide information for generating documents and messages which are delivered by the bank server 158.

It should be understood that ATM 146 may be operated through messages exchanged with plurality of servers which are connected to the network 156. This may include other bank servers directly connected to the network 156 as well as bank servers which are connected to a further network 162 which can be transmitted through a control server 164. An example of such

a system would be a system in which network 162 is a wide area network such as the Internet and control server 164 serves as a firewall limiting the servers from which the automated teller machine 146 may receive instructions.

It should further be understood that the document handling portion 154, device server 152 and device manager/interface component 150 may in embodiments of the invention comprise components which communicate through the operating system of the computer on which the components reside, or may communicate on a local area network which operatively connects the components of the machine. It should further be understood that in other forms of the invention the machine may be connected directly to the wide area network.

In the exemplary embodiment of the invention shown in Figure 10, the server component associated with an image recorder device resides on the computer which operates at least some of the transaction function devices of automated teller machine 146. An image server component 166 is resident on the computer within the automated teller machine and is accessible through the network 156 at an address on the machine. As in the prior embodiment, the image server is in operative connection with at least one data store 168. The data store 168 includes executable instructions carried out by the image server as well as image and transaction data. It should be understood that the data store 168 may represent a portion of overall memory available in connection with the computer operating the automated teller machine 146. Alternatively data store 168 may include a separate data store such as a recorder with a removable storage media or a combination of allocated storage available on the computer in the machine and a separate data storage device.

It should be understood that in certain embodiments of the invention the computer in the automated teller machine 146 operates in a Microsoft Windows NT® software environment and data storage is allocated between the components operating in the machine. Further the transaction data storage associated with the captured images accessible through the image server is shared with other transaction data storage maintained for transactions carried out by the machine, to reduce duplicate storage of data. Such transaction data storage information may be stored in the machine for purposes of archiving or accumulating batch data which may be later transferred to the back office 160 through the bank server 158 or to other locations. It should further be understood that in embodiments of the invention, image data may be downloaded to other devices connected to the network 156 and accessed therefrom while transaction data may be maintained in storage at the ATM or in a different data store within the network. The downloaded data may be erased or overwritten after downloading to provide added storage space at the machine. Alternatively image data may be downloaded with or at generally the time of each transaction at the machine.

The exemplary form of the invention enables accessing image and transaction information from different locations. This is accomplished by coordinating image data and transaction data which may be accomplished in embodiments of the invention by including with the image data, data representative of source as well as information corresponding to a time associated with the transaction as previously described. This enables correlating the image data with the source transaction data corresponding thereto based on time and date. Of course other alternative approaches to recovering and correlating transaction and image data may be used.

As shown in Figure 10 image server 166 is connected to a hardware interface schematically represented 170. Hardware interface 170 is shown connected to cameras 172 as in the previous embodiment. Hardware interface 170 of the exemplary embodiment performs the switching, acquisition control, digitizing and hard trigger receiving functions described in connection with the previous embodiment. Interface 170 may also be used to provide outputs for controlling camera aiming devices (such as pan/tilt/zoom), focus devices, lighting and other devices. It should be understood however that the allocation of such functions between a plurality of hardware and software components may be achieved in various ways within embodiments of the invention.

In the embodiment shown in Figure 10 the image server 166 is in operative connection with components 150, 152 and 154 which are primary operational components of the ATM. Such configuration readily enables configuring the image server to cause the capture of image and/or transaction data in response to soft triggers which are in the form of events which are fired to components in connection with the server. Such programming may be readily accomplished through visual programming tools used in connection with programming in JAVA and other languages. Such programming tools may include Visual Age® by IBM and Visual Studio™ by Microsoft. Use of such programming enables readily establishing and changing the soft triggers for image and other data acquisition as well as readily changing actions which may be taken in response thereto.

As shown in Figure 10 other terminal devices may be connected to the network 156. This may include user terminals 174 of the type previously described as well as verification terminals, data storage terminals and other types of terminals that work in connection with the system.

Network 156 may be connected to interface devices schematically represented 176, which provide gateways to other communications mediums of the type previously described. Such gateways may be used for sending messages to servicers, police authorities or other persons who are to receive messages in response to events which occur at the ATM based on the sequence of configuration data for the capture of image data stored in connection with the image server or other computer.

As can be appreciated from the configuration in Figure 10 an authorized user operating a user terminal can access image data by accessing the image server with a browser and recovering image data from memory. This configuration further facilitates analysis of image data by being able to correlate transaction activity and the operation of transaction function devices with image data. Further the capability of the exemplary embodiment of the invention to capture image and transaction data while virtually simultaneously delivering image and transaction data to a remote user, facilitates maintaining ATM 146 in operation. Actions in response to triggering events may include panning, tilting or zooming cameras which may be used to verify suspect lack of usable video events or as actions in a sequence. Other advantages of this embodiment due to the flexibility and the ability to readily make changes in configuration will be appreciated by those skilled in the art.

An alternative form of the system of the invention generally indicated 178 is shown in Figure 11. The system 178 includes an automated banking machine which is an automated teller machine generally indicated 180. ATM 180 is similar to ATM 146 previously described except as discussed herein.

ATM 180 includes a computer which includes an image server 182. Image server 182 operates in a manner similar to image server 166. However image server 182 instead of acquiring image signals through a hardware device obtains image signals from a connected network 184. In the system shown in Figure 11 cameras 186, 188 and 190 are each connected to a mini server 192, 194 and 196 respectively. The cameras and mini servers are each operative to function as a network node in connection with network 184. Each network node includes hardware and software which converts the camera signals to image pages or similar image files that can be transmitted through the network 184. These images can be relatively spaced in time or close enough together to be considered as full motion. The programmable instructions executed in connection with image server 182 are operative to selectively access the cameras through the associated mini server and to download images therefrom. Such images may be stored as image data in correlated relation with transaction data in the data store within the automated teller machine. Alternatively image data may be stored in data stores associated with each of the mini servers so that it may be selectively accessed therefrom by image server 182 as well as from other authorized terminals within the network.

As can be appreciated, this alternative configuration further distributes the acquisition of image data and transaction data. However as the transaction data is accessible through the image server 182, and the system location of the mini servers 192, 194 and 196 are each known from their associated URL or similar system address, correlation and recovery of image and transaction data may be readily accomplished. It should further be understood that while in the configuration of the system shown in Figure 11 each camera is shown with an associated mini server, a group of several cameras may be interconnected and may selectively deliver image data

through a single mini server to the network. Alternative configurations may be used to suit the particular nature of the system being operated.

Figure 12 shows yet another alternative system of the present invention generally indicated 198. System 198 includes an automated banking machine which is indicated as ATM 200 which may be generally similar to ATM 146. ATM 200 is connected to a network 202. A computer including an image server 204 generally similar to image server 166, operates on ATM 200. Cameras 206, 208, 210 and 212 operate to supply camera signals which are received by image server 204 through an interface 214. In this embodiment the interface 214 is an interface to a second network schematically indicated 216 in which the cameras are connected. The interface 214 in one form of the invention is an interface to a power supply network to which cameras are connected. Interface 214 may be for example an interface to a power distribution system within a facility in which the ATM is operated. An X-10 technology type of communication may be used for example. Signals from the cameras 206, 208, 210 and 212 are superimposed on the power distribution line through a plurality of impedance matching interfaces 220, 222 and 224 respectively. Signals sent by interface 214 are operative to cause selected ones of the cameras to output camera signals superimposed on the power distribution lines. Such image signals may be received at interface 214 and processed in the manner similar to other camera signals as previously described. Camera signals sent in the second network may take various forms of analog and digital signals and may be multiplexed or otherwise sent simultaneously so that image data may be acquired and captured selectively by each of the cameras as described in connection with the previous embodiments. Signals for controlling or positioning cameras may also be transmitted through the network as well as image data.

Figure 13 shows yet another form of the invention referred to as system 226. System 226 includes an automated banking machine 228. Machine 228 is an ATM similar to ATM 146 except that it includes among its transaction function devices a check or other document imager schematically indicated 230. ATM 228 operates to accept checks or other instruments from users of the machine in response to control by the other components. The imaging device 230 operates to produce document image signals representative of documents that may be deposited or received by a user in the machine. An image server 232 or a computer in which it operates is operative to cause the capture of images produced by the imaging device and store image data responsive thereto in the associated data store. In addition, the computer is operative to cause the machine to capture transaction data and/or to correlate transaction data captured by other components of the machine, with image data. Image server 232 and the associated computer may also operate in connection with cameras and other input devices similar to those discussed in connection with the previously described embodiments. The computer may further store camera image data in memory in correlated relation with document image data generated from the imaging device.

Image server 232 is in operative connection with a network 234. Network 234 is in operative connection with a terminal 236. Terminal 236 may serve as a document verification terminal. Terminal 236 has in connection therewith a verification data store schematically indicated 238. Verification store 238 includes therein data representative of indicia which can be used to verify genuineness of documents input to the machine through the imaging device. For example verification data store 238 may include data representative of customer signatures and/or other identifying data for customers authorized to provide checks into the machine.

Document verification terminal 236 includes a computer including a browser therein.

The terminal 236 is controlled responsive to input devices that access document image data through the image server 232. The document verification terminal 236 operates responsive to the document image data to compare indicia in or associated with the document image data, to

5 indicia stored in the verification data store. This may be done for example by comparing image data related to checks or similar documents input to the check imager 230 to images of known genuine signatures stored in data store 238. Such indicia may be compared for genuineness by human comparison on a side-by-side basis by outputting such information to an output device such as a screen. Alternatively the data may be manipulated to place such signature data in  
10 overlapping relationship or in other relative positions so as to facilitate analysis thereof.

Alternatively, verification terminal 236 may include instructions such as software programs which are operative to compare indicia in document image data to indicia stored in data store 238. Such verification software may compare the signature data from the input document and the known genuine signature and provide an indication of suspect signatures or possible forgeries.

15 This may be accomplished by comparing the image data corresponding to contours of letters, portions of letters or combinations of letters within a signature, and indicating when a level of correspondence does not exceed a particular threshold.

Image server 232 may have associated instructions which causes document image data to be provided automatically periodically to verification terminals 236. Alternatively image server  
20 232 may be configured to operate in connection with other components of the machine to provide an indication during a transaction involving an instrument, and to forward such document image information through the network 234 so that the character or genuineness of the deposited

document may be verified before the transaction is completed. This has the advantage in that when cameras are used in connection with the machine, an image of the individual operating the machine as well as the document image data may be viewed or processed before crediting or charging the customer's account for the value of the deposited or dispensed document respectively. The ability to capture the image of the customer along with the document image and to store the two in correlated relation further facilitates tracking and minimizes fraud. In addition, the verification terminal 236 may operate in the manner previously described in connection with user identification software which enables identifying a user by physical characteristics. This further minimizes the risk of fraud.

It should be further understood that although the exemplary embodiment has been described in connection with a document imager and an attended verification terminal 236, embodiments of the invention may operate using unattended verification terminals such as terminal 240 which operates to carry out verification activities according to stored instructions without human interactions. Alternatively other forms of the invention may verify the authenticity of deposited documents through watermarks, holograms, inks having magnetic, fluorescent or other characteristics or other indicia which is indicative of genuineness of deposited documents. Other approaches and configurations may be used depending on the nature of the documents being accepted or dispensed and the indicia which must be compared or processed in order to determine the genuineness of the accepted document.

It should further be understood that features of the system shown in Figure 13 may be applied to systems in which documents are printed with identifying indicia so as to enable more ready verification of their genuineness. This may include for example printing an image of a user

on a check or other document dispensed by the machine. This may be done by the image server in response to image data from a camera which has the user in its field of view during the transaction. Such image data may be delivered by the image server to the printer which is one of the transaction function devices in the machine. The image data may be used by the printer to produce a document which includes the image of the authorized user. This reduces the risk of the document being presented by unauthorized persons. In addition or in the alternative a computer in connection with the image server may obtain image data concerning an authorized user, watermarks or other information from memory or from terminals connected to the network 234 or may generate one or more identifying numbers or other indicia, and include such information or indicia in printed documents it produces.

Further alternative forms of the invention enable correlating image and transaction data for documents received or produced by the machine. This enables users at other terminals which have access to the network 234 to verify the appearance features, such as the appearance of a person to whom a document was issued. This enables persons accepting such documents to verify the authority of the person presenting the document to possess it. In addition if the document is redeemed at another terminal, the image of the person redeeming the document may be compared to the image of the person who received the document to verify that the document is being redeemed appropriately. This may be done visually using an output device at the terminal where the document is redeemed or may be done at a remote verification terminal in the network by an operator or by image comparison software. Alternatively identifying indicia in a presented document may be checked for genuineness and/or validity. For example, the redemption of

documents may be recorded and tracked, so that upon presentment a check is made as to whether the presented document has already been redeemed.

Similar principles may be applied with regard to data representative of value which is loaded onto smart cards or similar instruments. Data representative of the image of the person who has received the value may be stored in correlated relation with indicia corresponding to the transaction in which value is loaded and/or with identifying indicia associated with the card.

Later when an individual presents that same card at the same or a different terminal, an image of the person presenting the card may be captured and/or the appearance of the person may be compared to the image data stored in memory. Image data of the authorized user may also be stored in memory on the smart card. Such image data may correspond to facial features.

Alternatively image data may correspond to other features that are capable of being viewed by eye or read with the aid of a machine such as fingerprints and iris scans. Similar principles may be applied to other types of transaction systems and devices to minimize the risk for fraud and abuse.

Forms of the present invention may enable the management of available memory to minimize the risk that image data and/or transaction data related to transactions conducted at the machine will not be captured and stored in memory. Figures 14 and 15 schematically represent steps performed by certain forms of the invention to manage the amount of memory resources and to selectively off-load image data when necessary. In addition the exemplary form of the logic described in connection with Figures 14 and 15 is operative to estimate when memory resources such as a permanent image storage medium will become full based on transaction rates, and to forward a message to appropriate personnel of such impending loss of memory capability.

Referring to Figure 14, the logic flow commences with a step 242 in which a decision is made as to whether image data has been stored. If so, a determination of available memory is made in a step 244. In addition a record is made as of the available memory as of the time and date of the transaction. This is done at a step 246. The decision is then made at a step 248 as to whether the available memory is below a particular threshold. If so, certain actions are taken as described in connection with Figure 15.

If the available memory is not below the threshold as determined in step 248 a determination is made at a step 250 to calculate memory use over the preceding set number of days, hours or other time period. At a step 252 the calculation is then made as to a time to depletion (TTD) based on the current rate of memory use. The determination is then made at a step 254 as to whether the time to depletion (TTD) is less than a set number of days. If so, actions are taken similar to those taken when the available memory is below a threshold as described in connection with Figure 15.

If the time to depletion is less than the set threshold, the logic flow then operates to recall from memory historical use pattern data. This is done at a step 256. This historical use pattern data may be information regarding the level of use of the memory based on the day of the week or other correlatable data for the machine over a period of time. Such pattern data may involve fuzzy logic or other programming which may make allowances for pay periods, holidays, vacation periods and other activities which are used to establish the historical model on which the pattern is based. Using the historical pattern data the logic flow calculates an estimated time to depletion based on the pattern data in a step 258. The time to depletion based on the pattern data is then compared to the threshold in a step 260. If depletion is expected to occur based on

the pattern data in less time than the set threshold, action is taken. If the time to depletion is longer than the set threshold the pattern data is updated in a step 262 and the logic flow is repeated the next time a transaction occurs.

It should be understood that although in this described logic flow three determinations are made as to available memory, in other embodiments a lesser number of tests or additional tests may be made. In addition the tests may be correlated or combined using fixed or fuzzy logic type principles to calculate a time when depletion is expected.

In the event that there is concern about lack of memory as determined in steps 248, 254 or 260 a determination is made at a step 264 concerning whether the instructions associated with the image server include executing an image download sequence prior to the memory reaching capacity. If so an image download sequence is executed at a step 266. This image download sequence may be to a remote terminal through the network. Alternatively the download sequence may be to a hard or soft permanent or temporary storage device. Such download sequence also includes clearing the portion of the memory that becomes available after data is downloaded or otherwise allowing the memory to be overwritten such that additional image data may be stored. Banking machine data which identifies the particular machine which generated the image and transaction data may be added to or stored in correlated relation with the downloaded data in accordance with programmed instructions to facilitate analysis after the data is downloaded.

If the computer and associated image server is not configured to conduct an image download, a determination is made at a step 268 concerning whether available memory may be reallocated. In some circumstances the memory allocated for storage of images may be expanded to include additional memory. This may include for example a dynamic reallocation of memory

storage by the operating system of the machine based on resources being utilized. Such memory may be allocated on a temporary or permanent basis. If memory reallocation functionality is provided a reallocation sequence is executed in a step 270.

If memory reallocation is not available a determination is made at a step 272 as to whether a notification message concerning impending depletion of the memory has been sent within a given time window. If a message has been sent within the time window then no further action is taken. However if a message has not been sent within a given time window a message is formulated by the image server at a step 274. This message preferably includes data as to the particular machine and when the available memory will reach depletion based on the current rate of transactions, historical data, threshold value or other basis upon which the determination to send the message was made. After the message is formulated the device server executes the message sequence and operates to send the message to the users who are to receive it based on the image server configuration and the instructions stored in the system. Generally such messages will be sent as one or more e-mail messages to selected e-mail addresses in the network. Of course in alternative embodiments other types of messages may be sent.

Figures 26 and 27 show examples of user screens which are presented by the image server to user terminals as part of a configuration sequence. Through use of the templates established through these setup screens users are enabled to configure individual e-mail and group e-mail lists. These lists include persons to be notified in the event that particular events occur. The notification of particular individuals at e-mail addresses is included as part of the timing and sequence instructions stored in connection with the image server which determine what is done in response to particular events.

As later discussed in detail alternative forms of the invention may operate to selectively delete stored image and/or transaction data. For example, transactions may be identified by selected parameters and image and/or transaction data associated with those transactions may be deleted. This may be done based on parameters such as elapsed time since the transaction was executed. Alternatively, transaction data may be deleted based on the type of transaction, amount or other triggering event associated with the image data. Thus, for example, data associated with withdrawal transactions which are under a certain amount and which occurred more than a particular number of days previously, may be deleted in response to programmed instructions. This frees up available space for storing data associated with additional transactions while preserving image and/or transaction data related to other transactions which may be more significant. Similarly, image or transaction data captured in response to other types of triggering events such as alarms, servicing activities or other conditions which correspond to a particular parameter or combination of parameters may be stored for longer periods of time prior to deletion and/or downloading from a local memory. Various parameters for the preservation or deletion of data may be developed based on the nature of the system, the transactions conducted and the needs of the system operator.

Alternative embodiments of the invention may operate to advise a person who is setting up sequences or operation of the system, about how long the system will be able to run before image data will need to be deleted or off loaded. The computer operating to store data or in connection therewith, may store historical use data for the ATM or other machine. Such historical use data, combined with the number of images that the system is configured to capture and the degrees of associated data compression (as well as possibly other data) may be used to

calculate a period of time until the available memory is used. Alternatively, and particularly when no historical use data is present, the computer may be programmed to prompt a user to provide estimates of the number or frequency of triggering events and/or transaction rates. This information may be used by the computer to calculate how long the system can operate without deleting or off-loading images. The user in response to the output of such estimates may choose to change settings or sequences to capture more or fewer images in response to each transaction or event, or to change the degrees of data compression. In addition the computer may be configured to send a message to a selected user or address if transaction rates change from the historical or estimated rates by more than a set amount, and advise of the time period available based on the actual rate of memory use. In response to such a message a user may choose to reconfigure the system.

The described form of the present invention presents a useful user interface which may be used to set up the system configuration. Generally such configuration is established from a user terminal which is connected to the image server through a network. In this example the image server configuration provides for three levels of activities which users are authorized to perform. These levels correspond to categories of privileges and are “administrator”, “operator” and “service”. A screen 278 shown in Figure 16 shows the categories of activities and the user groups which are permitted to perform them in accordance with the configuration of an exemplary embodiment of the invention.

As previously discussed, certain forms of the invention enable the configuration to include timing and sequence data which specifies what images and data to capture, as well as what further actions to take in response to certain triggering events. Figure 20 shows a screen

280 which may be displayed at a user terminal to establish a sequence of events that occur in connection with particular events. Such sequences may be programmed so that the sequences are different based on the day of the week and/or the time of day.

In accordance with the user interface in this exemplary embodiment, sequences are  
5 programmed by establishing a daily schedule of what is to occur in response to events. Figure 21 shows a screen 282 which is presented in response to clicking on the “daily program” icon from screen 280. Screen 282 enables a user to configure the program to establish what is to occur if particular events occur within a given time window. In programming of this embodiment, if multiple sequences overlap days, the narrowest schedule overrules broader schedules. For  
10 example if a schedule is configured for weekdays but a different schedule is configured for a specific day, the specific day schedule will overrule the general schedule for that day. Likewise to prevent inadvertent overlap of sequences, the programming of this embodiment provides entering only a start time for a sequence. An end time is not required and a sequence will continue until a new sequence is begun. Figure 22 shows a screen 284 used in an exemplary  
15 embodiment of the invention. Screen 284 is generated responsive to selection of the “every day icon” from screen 282.

Actions in a sequence are established by selecting the “setup sequence” icons shown in screen 284. Selecting such an icon that is active generates a screen 286 of the type shown in Figure 23. Screen 286 enables a user to establish the degree of data compression for images  
20 captured during the sequence. The compression level can be modified such that different sequences of events cause images to be captured at different compression levels which produce different image quality levels. Generally the less the data is compressed the higher the image

quality. However available memory is used more quickly when the degree of data compression is less.

In this exemplary embodiment of the invention a plurality of actions may be added to a sequence by clicking on icons such as “add camera”, “add output” or “add e-mail”. In alternative  
5      embodiments, additional actions may include “repeat sequence” and “wait” type actions.

Clicking on such icons changes the system configuration so the system will take actions in a sequence such as those previously discussed. Such sequences may include for example input of instructions for capturing images from cameras, sending e-mails to individuals or groups of individuals, providing selective outputs to the control devices, or sending messages through the  
10     network. As can be appreciated from screen 280 various sequences may be executed responsive to triggering events such as detection of motion in fields of view of various cameras, the blocking of one or more cameras (at any time or during a time of desired image capture), in response to various transaction functions carried out by transaction function devices or on a periodic time schedule. Screen 288 shown in Figure 25 is an exemplary screen presented at a user terminal  
15     which enables a user to set up the transaction data to be captured as well as to facilitate communication between the image server and the automated banking machine. Of course various types of transaction data can be selectively captured. This is done from screen 288 by selecting types of transaction data to be captured. Image data may also be captured in response to the operation of selected transaction function devices and responsive to the type of transaction  
20     function devices resident in the machine.

In the event that the sequence configuration includes sending e-mail messages to selected addresses, the image server is operative to send such messages in accordance with e-mail

information which has been stored in connection therewith. Screen 290 shown in Figure 26 is a template for a user to use in inputting e-mail address information for individuals. Individual e-mail addresses may be combined into e-mail groups and a screen 292 shown in Figure 27 may be accessed to show the groups of individuals who are notified responsive to events which may occur at the terminal. The configuration of the terminal is such that a plurality of individuals may be sent an e-mail message in response to the occurrence of a single event or other activity at the terminal. This facilitates the notification of individuals in the event that several individuals may be required to respond.

As previously discussed, the timing aspect of programmed sequences enables different individuals to be notified of events at different times and on different days. This facilitates notifying the persons who have the most direct responsibility for the condition at the time it occurs. Forms of the invention may also be configured to attach or include in e-mails, images which correspond to the triggering event which causes the notification to be sent. This may immediately provide the person receiving the e-mail with useful information about what is occurring at the machine. A series of images or applets for the modification of images may also be transmitted with the notification. This may include for example images which occurred prior to the triggering event. Such e-mails may also include information about the nature of the triggering event, the location or banking machine where such event is occurring and other pertinent data. In this way, the entities notified will receive a record of what has or is happening at the machine. This record will also be available even if the machine is compromised and rendered inoperative shortly thereafter. Embodiments of the invention may also include with such image files, digital watermarks or other indicia of authenticity so that the accuracy of the

information provided and the images associated therewith have enhanced assurances that they have not been tampered with. Further, included in e-mails or attachments thereto may be sound or other files with which images are associated. This may be accomplished through the programming of sequences which include the capture of audio or other data in response to the occurrence of triggering events. Numerous alternative approaches may be taken utilizing the principles of the invention. Of course, embodiments of the system may carry out communication in ways other than through e-mail such as by RF, fax or simulated voice communication through telephone connection.

As previously mentioned, security associated with the image server may be important to prevent accessing by unauthorized individuals. In the exemplary form of the invention password protection is provided to minimize the risk of unauthorized use. Of course in other embodiments other security techniques such as public key encryption, encryption of image and transaction data and digital signatures may also be utilized. Figure 24 shows a screen 294 which is used in embodiments of the invention to establish access for particular users. A system administrator is enabled to gain access to screen 294 and to input information concerning additional users. Screen 294 also enables the system administrator to establish passwords to be used by each authorized user.

Embodiments of the invention may also restrict certain users, or certain categories of users, in the type of image data that may be reviewed. This may be done in exemplary embodiments by limiting access to image and/or transaction data selectively to users, based on the types of triggering events associated with the storage of images. Alternatively, certain users may be precluded from viewing images captured from certain cameras. This capability may be

used to prevent certain users from observing certain images such as images which may include customer PINs or the combination to a lock on an ATM. By preventing selected users from accessing certain image data based on the type of triggering event or camera associated therewith, images captured by the system that need not be restricted may be made available more  
5 broadly and used for potentially more purposes.

A useful aspect of embodiments of the present invention is the ability of the system to provide screens or displays of image and transaction data that can be readily sorted, viewed and analyzed at user terminals within the network. Figure 17 discloses a screen or display 296. Display 296 includes sets of images 298, 300, 302 and 304. Each image set includes  
10 “thumbnails” of five images. Each set corresponds to a transaction carried out by a particular user and each set of thumbnail images which comprises a set, corresponds to images of the particular user during that transaction. Of course it should be understood that in situations where the timing and sequence programming require a lesser or greater number of images, the number of images which comprise a set may differ. In addition as previously discussed, some  
15 transactions or triggering events may have no corresponding images at all. Other events which do not correspond to ATM transactions may have a large number of images spaced closely in time depending on the configuration of the system. This may include full motion or image frequencies approaching full motion.

The images which have been captured and stored by the system may be preferably  
20 arranged in one or more series. A series may be a collection of all stored images arranged chronologically. Alternative series may be produced by segregating images that correspond to one or more types of triggering events or transaction parameters. Images included in such a

series may be ordered chronologically, may be ordered in a hierarchy in accordance with one or more search parameters, or other ordering scheme. A useful aspect of some embodiments is that the user terminal enables a user to scroll through a series of images, displaying one or more of the images on the display at a time, by selecting certain icons with an input device. The icons  
5 enable the user to selectively display images and to move to display one or more different images at points forward or backward in the series from an image or images currently being displayed. In exemplary embodiments, selection of certain icons cause the display to change and display images in different increments and in different directions in the series from one or more images currently displayed.

10 In an exemplary embodiment screen 296 includes icons 306, 308, 310, 312, 314 and 316. The icons may be used to selectively scroll through sets of images and images in the sets. As explained with reference to an exemplary help screen 318 shown in Figure 18, selecting icons 310 and 312 enable scrolling backwards and forwards respectively by one event. Selecting icons 308 and 314 enable scrolling backwards and forwards respectively by an increment of ten events.  
15 Icons 306 and 316 enable scrolling backward and forward respectively to the beginning or end of a series of events or images.

Exemplary screen 296 also includes “jump to image” and “jump to event” input boxes 320 and 322, respectively. As explained in Figure 18 boxes 320 and 322 may be used to select images that are to be displayed. A “save comments” box 324 is used to selectively store  
20 comments in correlated relation with particular images. Comments can be manually input, input by voice as sound files, input through voice to text conversion software or may be generated and stored in response to programmed instructions based on parameters and/or triggering events. .

Screen 326 shown in Figure 19 shows a selected image 327 which has been enlarged by selecting one of the images from the sets. This may be done in the described embodiment by clicking on an image with a mouse or through other inputs. As shown in screen 326, the enlarged image 327 is displayed with corresponding transaction data which corresponds to the image. In addition event and image data corresponding to the image is also displayed. A user reviewing the image data is enabled to review any of the available image and transaction data.

Advantages of the described embodiments of the present invention include the ability of a user terminal to access image and transaction data selectively. For example through operation of the browser or other programs within the user terminal an authorized user is enabled to search for selected parameters such as user name, account number, time and date and other data which may be stored in the data store. Image and transaction data may also be searched by combinations of parameters or ranges of parameter values. This enables the operator of the user terminal to find selected image data rapidly or more selectively, and without having to scan through large volumes of information. In addition the exemplary forms of the present invention enable holding image and transaction data for substantially longer periods of time with minimum inconvenience. As a result this enables such data to be analyzed for much longer time periods and potentially much more inexpensively than is currently possible.

A further advantage of preferred forms of the present invention is that image data is readily accessible and searchable. This facilitates identification in connection with issued documents such as bank checks or value loaded to smart cards as previously discussed. This enables users having access to the data to verify that a document or other item is being presented

by an authorized user by accessing and visually or automatically comparing image data. Further advantages and novel aspects of the invention will be apparent to those having skill in the art.

Figure 28 shows yet another example of a system of the present invention designated 328. System 328 is similar to other systems of the invention previously described except as discussed herein. In system 328, image capture and delivery functions are performed by a separate device 330. Device 330 in this embodiment includes one or more computers or processors therein including one or more servers, and is operative to capture and store image data, transaction data and other information from devices to which it is connected. Device 330 also includes appropriate interfaces to communicate with the devices to which it is connected for purposes of receiving inputs and outputs. As schematically indicated in Figure 28, a computer included in device 330 is in operative connection with a data store for purposes of storing instructions as well as image and transaction data. It should be understood that while a single device for performing the functions is shown in system 328, other forms of the invention may include a plurality of operatively connected devices including a plurality of processors and operatively connected data stores as well as other computers and interfaces, to perform the functions similar to that of device 330 described herein.

In system 328, device 330 is connected to one or more automated banking machines schematically indicated 332. Automated banking machine 332 is similar to the machines previously discussed and includes a plurality of transaction function devices. Automated banking machine 332 may have one or more cameras or other image capture devices adjacent thereto as represented by camera 334. As will be appreciated, a number of cameras may be positioned adjacent to the machine by being within and/or near to automated banking machine

332 for purposes of capturing image data related to users, documents, surroundings or other types of visual inputs that may be desirable to capture and analyze. Camera 334 is operatively connected to device 330 such that device 330 may receive and capture image data therefrom. It should be understood that additional types of data capture devices may also be included adjacent to or within automated banking machine 332. This may include for example microphones for capturing sound or voice information as well as devices which capture data related to transactions. Embodiments of the present invention can use voice recognition software to detect sounds from the microphone representative of words or the stress levels of sounds emanating from persons near the automatic banking machine. Such voice or sound data may be used in combination with images or other data to further detect and evaluate conditions at or near the automated banking machine. The data or information which is captured is also communicated to the device 30 through one or more appropriate electronic connections schematically indicated 336.

In addition to capturing images or other data from one or more automated banking machines, system 328 may also be operative to monitor one or more other transaction devices, as well as to monitor and record activities which occur within a facility. One or more cameras represented by cameras 338, 340 and 342 are shown and are representative of cameras used for this purpose. The cameras may be used for capturing images in response to triggering events, which may be either hard or soft triggers from one or more types of input devices. Alternatively, the cameras may capture images on an ongoing basis in one or more sequences for purposes of providing a generally continuous record of overall activity within an area. As in the previous embodiments, this form of the invention also provides the capability of capturing images from

multiple cameras generally simultaneously as well as the capability to both capture images and be delivering messages or image data from the device 330 on a generally simultaneous basis. As will be appreciated, the capabilities of the system may be increased by the addition of components or enhanced capabilities of the components which comprise device 330. This may include, for example, additional interfaces for digitizing image data received from cameras, additional and faster interfaces for input and output devices and increased processing capabilities and data storage to facilitate enhanced function. The required capabilities of device 330 depend on the particular type of system that a user desires to operate and the number and type of connected cameras and other devices.

In the exemplary embodiment shown, a number of different types of input devices are provided. These input devices provide inputs indicative of one or more triggering events to device 330. Such triggering events cause or may affect the manner in which image data is captured by the system. Generally the input devices include appropriate interfaces in connection therewith to enable the device 330 to receive signals indicative of the triggering event. The exemplary input devices shown include a cash register 344. Cash register 344 which may also be considered a banking machine, is connected to device 330 by a communications link such as a local network. This enables the device 330 to cause images to be captured from a corresponding camera when signals indicative of transactions are occurring at the cash register. It should be understood that cash register 344 is representative of but one of numerous types of devices that may be used in a sales, service provider or banking environment and for which it may be desirable to make a record of activity occurring adjacent to such devices when activities are conducted.

Additional representative input devices include sensors schematically indicated 346.

Sensors 346 may include sensors for detecting the opening of doors, windows, ventilation ducts or other activities for which it is desired to capture images. Another exemplary input device includes an alarm input 348. The alarm input 348 may be, for example, a device which is  
5     actuated by person to indicate an alarm condition. This may be, for example, a panic button which is pressed to indicate a hold-up in a banking or other establishment. Alarm input devices may take various forms and may include sequences input to computer terminals or other devices which are connected to device 330.

Sensors used in connection with the systems may include photosensors, infrared sensors,  
10     radiation beams or similar detectors. Such detectors may be used to sense when a person or item passes or occupies a particular space or area. For example, a detector may detect when an invisible beam type sensor is interrupted. Such an invisible beam may extend, for example, across a counter or bank teller window. As a result, a signal may be given to capture images in response to each occurrence of something passing over the counter or through the teller window.  
15     Similarly, such a beam may extend across a cash drawer or similar device. Alternatively, such invisible beams may extend in areas known only to an employee of the facility. This may enable the employee to give a signal to capture images (and perhaps activate an alarm) while not making physical contact with any device. Numerous systems may be developed using these principles.

Other input devices schematically indicated 350, may include other devices which detect  
20     or receive indications of activity and provide appropriate electrical outputs which can be received by device 330. These may include for example heat sensors, infrared sensors, weight sensing

pads, electronic beams or other types of sensors which can detect conditions for which an operator of the system may wish to capture images or other data.

In this embodiment of the invention, the cameras themselves may also serve as input devices. The cameras provide inputs which enable the detection of certain image conditions.

5 Image conditions may include for example, the detection of motion within the field of view of the camera. Alternative image conditions may include a lack of usable video. This may be for example a lack of contrast in an image, brightness or darkness beyond selected limits or other images or circumstances such as previously discussed. Alternatively as previously mentioned, image conditions may include the presence within a field of view of persons with particular  
10 clothing or features, the presence of persons with certain body orientations, the presence of certain objects such as weapons or the presence of particular types of colors or arrangements of colors. Numerous types of image conditions which may be determined through analysis of the digital images which are available from the cameras connected to the system may be used as triggering events.

15 In the embodiment of the invention shown, device 330 is also connected to output devices. Exemplary types of output devices shown include an audible and/or visual alarm schematically indicated 352. Such an alarm may give persons in an area notice of an alarm condition. An alternative form of an output device as shown may include lighting devices schematically represented 354. Lighting devices may be turned on for example in response to  
20 programmed sequences to illuminate an area where an alarm condition is detected.

Other types of output devices may include blocking mechanisms schematically indicated 356. Blocking mechanisms 356 may operate to block certain areas to prevent access or escape.

Alternatively in response to some alarm conditions as set through sequences programmed in device 330, other alarms may cause blocking mechanisms to open to facilitate escape of persons from selected areas. Other output devices include, for example, communications devices schematically represented 358. Communications devices 358 may include, for example, police  
5 alarms or dial-up devices to notify fire or security agencies of alarm conditions which are detected.

As schematically represented in Figure 28, device 330 is connected to a user terminal device 360. User terminal 360 may be used for providing inputs from users of the system as well as outputs to users, as later discussed in detail. Device 330 is also shown in connection with a  
10 network 362. Network 362 like other networks discussed herein, may be a communications link suitable for communicating, and may be a local network or a plurality of interconnected networks through which device 330 is enabled to communicate through an appropriate interface. Remote terminals 364 and 366 are connected to the network 362. The remote terminals may be used for providing inputs and outputs to the device 330. Such terminals may also be used for purposes of  
15 programming and receiving images from device 330 in ways which are later discussed. Other terminals in the network may be used to hold data which may be used to identify persons, signatures, documents or provide other functions or information as previously discussed.

It should be understood that system 328 is exemplary of many system configurations that are encompassed within the scope of the present invention. In one exemplary form of the  
20 invention, device 330 includes a Diebold AccuTrack™ digital video system which is commercially available from Diebold, Incorporated, the assignee of the present invention. Device 330 operates to provide a helpful user interface for communicating with and

programming the system. Such communications may be carried out through the interface at a local terminal such as terminal 360 or remotely from terminals connected to device 330 through a network such as terminals 364 and 366. Figure 29 shows an exemplary introductory screen 368 produced on an output device of a user terminal in connection with device 330. The user terminal, like those previously discussed includes a computer with a browser operating therein, which can communicate with device 330. Screen 368 provides a useful interface for a user of the system to configure the operation of the system. It also provides a useful interface with which users may interact to recover and sort images that have been captured by the system as well as to carry out other functions.

Screen 368 as well as other screens presented by the exemplary device 330 includes a set of icons and indicators referred to as a tool bar 370. As shown in greater detail in Figure 30, tool bar 370 includes a plurality of icons 372. Icons 372 include a home icon 374, a log-off icon 376 and an image search icon 378. Other icons included in the tool bar include a camera check icon 380, a system configuration icon 382, a system tools icon 384 and a help icon 386. Generally, the icons include an image or representation of an object which suggests to a user the function of each. For example, the log-off icon 376 includes a representation of a key that can be turned. The exemplary form of the search icon 378 is a representation of a pair of binoculars. Similarly, the icon 380 that is selected to conduct a camera check is a visual representation of a camera. Each of the icons 372 and the functions that a user is enabled to accomplish through the selection of each is explained in greater detail in Figure 31.

The tool bar 370 includes among icons 372 a status icon referred to as 388 in Figure 30. The status icon 388 indicates to a user the status of the system. Several status icons are provided responsive to the then current status of device 330.

The various status icons presented in the exemplary embodiment are shown in Figure 32. For example, a visual representation of a traffic light showing a green light 390 is displayed to indicate that the system is operating to capture images in the normal manner. A representation of a thermometer approaching the top of its range is included in an icon 392. This icon is displayed to indicate that the storage capacity of the data store within device 330 is reaching its maximum capacity and is not storing images in the usual manner.

An alternative icon 394 is displayed to indicate that there is a need for a user to exercise caution as the system is running with errors. Another icon 396 which is a visual representation of a diskette is displayed to indicate that input changes to the configuration of the device 330 have not been applied. An icon 398 which is a visual representation of a stop sign is displayed to indicate to a user that an application error has occurred or that some other problem has happened such that the system is not operating or communicating normally.

In this exemplary embodiment, a user at a terminal is enabled to program or configure operational features of the device 330. Preferably a user will be enabled to configure many features and operations of the system. This is accomplished in the exemplary embodiment by the user making selections and inputs from screens or pages in a graphical user interface through which a user sets up or changes the programming of the system. These interface screens and pages are displayed to the user responsive to selection of icons in the tool bar and through

subsequent selections as a user operates the automated banking machine in response to the interface.

In the exemplary embodiment, one of the aspects of the system that a user is enabled to configure is the period of time that image data and other data including transaction data is stored.

5 In this exemplary embodiment, the device 330 is configured to store data for at least certain programmed periods of time prior to deletion. Figure 33 shows an exemplary screen 400 which is presented to a user of the system. Screen 400 includes image type categories 402. The image type categories correspond to the types of triggering events which caused an image to be captured. For example, in Figure 33 the types of images corresponding to “normal” are those  
10 images that are captured in response to programmed sequences which are done periodically on a routine basis such as for a periodic surveillance of an area. Those image types which are captured in response to alarms correspond for example to images captured in response to trigger inputs such as a panic alarm or an intrusion into a secure area within a facility. Other image types correspond to transactions. These may include for example in the exemplary embodiment  
15 transactions conducted at automated banking machine 332 or at cash register 344. Through inputs in response to screen 400 a user is enabled to input and select which types of images are to be deleted first and last. The user is also enabled to set up minimum periods during which images corresponding to particular image types are to be retained.

Figure 34 shows an expanded screen 404 which further enables a user to configure the  
20 auto deletion feature of the invention. Through inputs in response to screen 404 a user is enabled to set the unit to accomplish automatic deletion of images in accordance with the parameters that have been input. The user is further enabled to input when the auto deletion activity is to begin

as well as when available disk space is considered sufficient such that auto deletions should stop. As a result in response to the user selecting to have auto deletion activity occur, the device 330 will operate to selectively begin deleting images in accordance with the priorities that have been established for the retention of images so that additional storage space may be made  
5 automatically available.

It should be understood that the parameters and deletion capabilities shown in connection with screens 400 and 404 are exemplary and other embodiments of the invention may operate to store image data and delete it selectively in response to other parameters. In addition, the auto deletion function may be combined or integrated with an automated downloading function so as  
10 to selectively transfer images prior to deletion to another storage area that is connected to device 330. This may include, for example, the transfer image and transaction data to other terminals connected in network 362 so that such image data may be stored at a remote location prior to deletion of the image data from the device 330. Other approaches and techniques appropriate for systems of the invention will be apparent to those skilled in the art from the foregoing  
15 description.

Another aspect of the exemplary embodiment that may be configured by an authorized user is the security applied to various types of images. In the exemplary embodiment device 330 allows a user to selectively apply authenticating algorithms to selected types of images. A screen presented to a user in the course of configuring the system to establish this capability is  
20 represented 406 in Figure 35. In response to screen 406, a user is enabled to set the system so that digital signatures are applied to any of several different image types. For example as represented in screen 406, a user may elect to include digital signatures in images captured in

response to triggering events such as alarm conditions, detection of motion or other hard trigger alarms. Likewise as shown in screen 406, the user may configure the system to apply digital signatures into images captured in response to transactions conducted at an automated banking machine. In the particular example, shown in Figure 35, digital signatures are not applied to  
5 “normal” images which are those captured in response to routine periodic sequences. As represented in screen 406, the user may also elect to apply digital signal security to no images or all of the images captured in the operation of the system. It should be understood that the categories of images shown in screen 406 are exemplary and in other embodiments other types of image parameters may be used.

10 A further useful aspect of the exemplary embodiment of device 330 and the system 328 represented in Figure 28 is the ability of an authorized user of device 330 to program sequences in which images or other information are captured. As is the case in embodiments previously discussed, sequences include a triggering event and a series of actions that are taken by the system in response to a triggering event. Triggering events may include, for example, sensing  
15 image conditions such as motion, lack of usable video or a blocked camera and taking a series of actions in response thereto such as capturing images from other cameras, turning on lights, placing in permanent storage temporary image data that was captured prior to the triggering event, sending messages such as e-mails or performing other actions. Similarly, triggering events may include activities conducted at an automated banking machine or other transaction machine,  
20 during which times it is desirable to capture and permanently retain images from cameras which have a field of view that includes the area where the machine is positioned. Similarly triggering events may include inputs to or from alarms or sensors. Other triggering events may include

sequences which operate on a timed or other periodic basis in a routine manner such that image data is stored in relatively permanent storage from each of the cameras in the system as a routine matter of course. Numerous types of sequences can be programmed by an authorized user using the exemplary embodiment of the invention.

5           For purposes of the particular exemplary embodiment of system 328, triggering events are cataloged by type as either “normal”, “alarms” or “transactions”. Normal images are those that are captured in accordance with routine sequences that are carried out on a periodic basis in accordance with the programming of device 330. Different routine sequences may be operative at different dates and times in accordance with the system configuration. Such routine sequences  
10           may, for example, capture an image from a particular camera so as to store it in relatively permanent memory every so often, then subsequently capture an image from another camera and so on. Because these “normal” images are captured on an ongoing basis, care is generally exercised by the operator of the system to be sure that not so many images are stored that the available storage space is occupied too quickly by images that are of no particular interest.

15           The images classified as “alarms” are those that correspond to alarm type inputs. These can include hard trigger alarms such as those provided by switches, invisible beams and buttons that may be tripped as activities occur. Similarly, the category of “alarms” include image conditions such as motion detection, loss of usable video, detection of particular features, clothing, body orientation, colors or objects within the field of view (or a detection area smaller  
20           than an overall field of view) of a particular camera. Each alarm sequence may include appropriate actions such as actuating lights, blocking devices, alarms, contacting police or fire departments and/or sending e-mail messages and/or images to predetermined addresses.

In the exemplary embodiment, images associated with “transactions” are images associated with devices at which transactions are carried out. These may include transactions conducted at automated banking machine 332, cash register 344 or other devices where it is desirable to make a record of the transactions. With regard to transaction images the sequence typically involves a triggering event related to operation of a component of a transaction function device or terminal, and the actions may include capturing the image to store it in memory and perhaps additional steps depending on the nature of the transaction being conducted. Again, it should be remembered that the categories of triggering events in this embodiment are exemplary and other triggering event categories may be used in embodiments of the invention.

In the exemplary embodiment, device 330 operates in a manner like that previously discussed to digitize image data received from all or a selection of cameras on an ongoing basis. This image data is digitized as image frames on an ongoing basis and remains stored in the memory associated with the computer of device 330 for a fairly limited period of time. These temporarily captured and stored images may be more permanently captured by being moved to relatively permanent storage at the time that they are received or alternatively may be moved into relatively permanent storage at any time prior to their deletion. The value in digitizing and temporarily capturing images on an ongoing basis as often as possible from selected cameras include the ability to recover image data from a time prior to a triggering event. Thus for example if an image condition such as a blocked camera is detected, one or more prior images from the same camera that are still in temporary storage may be transferred in response to the triggering event to more permanent storage and correlated with data representing the triggering event. This may enable detection of an image which includes a person who caused a camera to

be blocked. The ability to retain on a more permanent basis images which occurred prior to a triggering event is configurable in the system, as are the number of images prior to the triggering event which may be transferred to more permanent storage. Of course the ability to transfer prior images depends on the number of image frames that are available in temporary computer storage from each camera prior to the deletion of such images. Of course the duration that such temporary images are stored can be increased with the addition of additional storage and processing capability. Likewise, the frequency of these temporary images from any given camera depends on the processing capabilities of the computer operating in device 330. Faster processing may similarly increase the frequency at which temporary images are captured.

A useful aspect of the exemplary embodiment includes the ability to program sequences using descriptive terminology which is established by a user of the system. Figure 36 shows a screen 408 that is displayed to a user in configuring system 328. Screen 408 is a camera set-up screen in which a user is enabled to give descriptive names to the particular cameras or field of view of a camera connected to the system. From screen 408, a user is enabled to select a camera through use of an input device such as a mouse and to “see” the field of view that is associated therewith. The user is also enabled to input a descriptive name for that field of view such as is shown in connection with “camera 01” shown in Figure 36. As subsequently explained in detail, a user is enabled to configure sequences including triggering events and actions to be taken in response thereto using the descriptive names that the user has given to various cameras in the system. This capability greatly simplifies the programming of the system as users are not required to learn any special conventions or terminology.

As is the case with cameras, users are also enabled to apply descriptive names to outputs which are provided from the device 330. These outputs may include for example a descriptive name for the particular item or action which is triggered by the output. For example, in Figure 37 there is shown a screen 410 in which an authorized user of the system is presented with output numbers for the various contacts and connections that may be made to device 330. By making an appropriate selection and input, the user is enabled to apply descriptive terminology to these outputs. For example, in screen 410 "output 01" has been named to indicate that it operates to turn on lights in a vestibule. Of course this is exemplary and any appropriate name may be input in the discretion of the operator.

Similarly, the user of the system is enabled to provide descriptive names for the inputs which serve as triggers for executing sequences by device 330. Screen 412 in Figure 38 shows the capability of a user to give a descriptive name to a particular input device. For example, in Figure 38 "input 01" to device 330 is indicated as associated with a teller panic button. Having this descriptive information available and usable to program sequences in the invention makes it much easier for a user to set up and check that the desired activity is happening in response to a triggering event in any given sequence.

Figure 39 also shows the capability of device 330 to execute sequences that are triggered by operation of automated banking machine 332. A screen 414 in Figure 39 shows an ATM monitoring set-up screen. In response to the presentation of screen 414, a user is enabled to give the automated banking machine a particular descriptive name. This descriptive name may include the particular street address where the automated banking machine is located. Similarly, if there are several automated banking machines at the same address, each machine may be

assigned a descriptive name representative of its location. Such terms used may include names such as “lobby ATM”, “drive-through ATM” and “walk-up vestibule ATM”. Of course many other types of names and designations may be used depending on the particular type of automated banking machine involved.

5           In the exemplary embodiment of screen 414 shown in Figure 39, the system 330 is shown configured to operate in connection with an ExpressBus™ interface which is used in automated teller machines manufactured by Diebold, Incorporated, the assignee of the present invention. Of course in other embodiments of the invention other appropriate set-up screens suitable for configuring the programming of the system to work with other types of machines may be  
10           presented.

          As was discussed in connection with other embodiments, actions performed as part of a sequence may include sending e-mails to one or several persons notifying them of the occurrence of the triggering event. Screen 416 shown in Figure 40 may be used by an authorized user of the system to input e-mail addresses that are to be notified of triggering events. Further as  
15           represented in screen 416, a user is able to designate groups of persons who are to be notified of particular events. These descriptive names for groups enable an authorized user to readily configure the system so that a number of people receive an e-mail message notifying them of a triggering event. Such actions are readily programmed into a sequence by referring to the name of the group.

20           Screen 418 shown in Figure 41 shows an example of an e-mail group which has been named “security”. This would be, for example, a group of persons or entities that are to be notified in the event that a triggering event detected by the system indicates a breach of security

or some activity that should be investigated by a security organization responsible for the facility. As can be appreciated by screen 418, an authorized user of device 330 is enabled to add, delete and edit e-mail addresses which compromise the groups which are to be notified.

The exemplary embodiment of device 330 enables an authorized user to readily program the system to carry out various types of sequences. These sequences include sequences associated with the capture of “normal” or routine images that are stored on a timed or other periodic basis while the system is operating. The user is also enabled to program sequences in response to the various types of triggering events such as inputs, motion detection, lack of usable video and the conduct of transactions. Figure 42 shows a screen 420 which is presented to a user in connection with establishing routine sequences for the capture of images and storage on a relatively permanent basis. Screen 420 also shows the beginning point for the programming of sequences in response to input devices which will be later discussed in detail.

In response to user selection of the “daily program” box in screen 420 a screen 422 shown in Figure 3 is presented. Screen 422 shows a visual representation of a weekly layout for hours in each day and the names of programs or sequences which are operated to capture routine or “normal” images during the indicated times. In addition to viewing the sequences that are operative at various times during the week from screen 422, the user is enabled to view the sequences applicable during any selected day of the week or in groups of days such as by weekdays or weekends. In the exemplary programming of the system, sequences are configured to continue until a time when another sequence is to be initiated. Further, the programming is set up so that a more specific program for a given time period will override a more general program during the selected period.

By selecting a particular day of the week from screen 422, the exemplary embodiment of device 330 is operative to display to a user a screen 424 shown in Figure 44. This screen shows for the selected day the sequences for the routine capture of images that occur on that day and the time periods when each sequence starts and ends. A graphical indication is also provided so that the user may readily see the times during the selected day when particular sequences are operative.

From screen 424, a user is enabled to select to view any of the selected sequences. For example, by selecting to view sequence indicated "1" in screen 424 the device 330 causes the screen 426 shown in Figure 45 to be displayed. Screen 426 indicates to the user a graphical representation of the steps involved in the routine sequence. Screen 426 also indicates the data compression level that is to be applied to the images that are captured and stored on a relatively permanent basis. By selecting the compression level the user may choose to have lower quality images in exchange for utilizing less of the available data storage space with images corresponding to the particular sequence. Various levels of data compression are selectable by the user for the sequence as shown in screen 426.

As represented in screen 426, the user is also enabled to set an image capture rate which controls the frequency of image capture and storage during time periods which are indicated in the sequence as periods during which images are to be captured by a particular camera. In the exemplary embodiment, the user has the option to capture a certain number of images or to set the system to capture images for a period of time. If the user configures the system to capture images based on time, the indicated rate reflects the number of images captured and stored in relatively permanent memory during each second. The exemplary embodiment also enables a

user to select AVI which is an image capture rate sufficiently high such that it appears to capture full continuous motion in a manner similar to a video clip. In the exemplary embodiment the capture of ten or more images each second corresponds to what generally appears to a user to be full motion. Of course, higher rates of image capture may be used.

5           Screen 426 represents the sequence which is carried out routinely by the system on an ongoing basis using the passage of time as the triggering event for each sequence. As can be seen, the particular cameras in the exemplary sequence are shown by the numbers as well as the descriptive names which have been applied by a user thereto. In this exemplary sequence, a camera which views a front door takes one image every second for three seconds. Thereafter, a  
10 camera which takes pictures of an outside ATM takes one image every second for three seconds. After that, a camera which views the back door takes one image every second for three seconds. After completing the sequence, the sequence repeats. An authorized user is enabled to modify the sequence by changing the number and timing of images in the sequence. The user is also enabled to delete and modify steps in the sequence by selecting the “buttons” at the bottom of  
15 screen 426. For example, a user is enabled to selectively or completely delete steps in the sequence, add cameras, add steps and save the revised sequence. Of course in other embodiments additional options for steps or actions in sequences may be provided.

          In the exemplary embodiment of the routine sequences, provisions are not made for notifying a remote location via e-mail. This is because routine sequences are continuously  
20 executed gathering and storing images at all times while the system is operating. This includes times in which images are being captured in response to other events. In other embodiments however, the system could include as part of the capture of normal images, provisions for

providing periodic reports via e-mail or otherwise, to functions or individuals who need to know that the system is operating normally. In addition, such messages may also include one or more images enabling the person receiving the message to visually verify the current condition in the area or facility monitored by the system.

5           Figure 46 shows a screen 428 at which a user is enabled to review sequences associated with inputs that correspond to triggering events. Such triggering events may include, for example, the inputs from various sensors sensing activity in various areas under surveillance, inputs from panic buttons or other types of inputs. By providing inputs in response to screen 428 an authorized user is enabled to selectively enable execution of the sequences in response to the  
10 triggering events which cause the listed inputs.

By providing inputs to screen 428 a user is enabled to configure the sequences associated with particular inputs. This includes establishing a schedule during which a selected input will cause a selected sequence to be executed. The schedule for the execution of a particular sequence is shown in screen 430 in Figure 47. Through inputs to screen 430, the user is enabled  
15 to indicate the time periods during which the system will execute the sequence if the input is received. For example, if the particular input is associated with opening a door, it may not be desirable to capture images during the time periods when the door is frequently opened by employees or customers who access a facility. The configuration associated with the input enables the input to cause the execution of the sequence only at the times when the capture of  
20 images is likely to yield useful information. In the exemplary screen 430 shown in Figure 47 an input number 2 is configured to cause its corresponding sequence to be executed only between

9 a.m. and 4 p.m. Through inputs to screen 430, an authorized user is enabled to modify these time periods as well as to select separate discrete times periods during which the input will cause the sequence to be executed.

The user is also enabled to set up or modify the sequence that is associated with the input.

5 This is accomplished from screen 430 by an appropriate input that causes the screen 432 shown in Figure 48 to be displayed. Screen 432 includes a description of the particular event which is associated with the input. Also as is the case with the routine sequences previously discussed, a user is enabled to set the image quality of the images captured and stored in response to the triggering event. Further in the exemplary embodiment, an authorized user is enabled to set the  
10 number of times that the sequence will be executed in response to the triggering event. As previously discussed screen 42 also includes provisions for the user to set the image capture rate associated with the capture of images that are done in the corresponding sequence on a timed basis.

The user is enabled to set up a sequence by selecting the “buttons” at the bottom of screen  
15 432. These buttons correspond to various actions related to cameras, outputs and e-mails that the system is enabled to capture images from, provide and send, respectively. In response to selecting one of these buttons, a particular configuration step or action which a user may populate with instructions by making selections therein is included in the sequence. For example, in response to selecting a “camera” button a sequence frame designated 434 in screen 432 is  
20 displayed. The sequence frame includes five areas for inputs that can be provided by the user. This includes the camera selection, the number of images, the frequency of the images and the duration or number of images involved. By populating these five spaces in the image frame with

data the user is enabled to provide the necessary programming information for carrying out an action in a manner that is readily understood in a sentence format. For example, as shown in screen 432, sequence frame 434 indicates that the camera designated “drive-thru #2” takes one image every one second for two seconds. Of course by making selections and inputs the user is enabled to change the five input areas within the sequence frame to suit their particular requirements.

Similarly, as represented in screen 432 selection of the “output” button enables a user to include a sequence frame 436 in an action the sequence. The sequence frame includes three inputs that can be made by a user to select the nature of the output that is to be included as an action in the sequence. In the case of sequence frame 436 the user is shown as having populated the information for causing the “W station # 2 light” to turn on for ten seconds. Thus again the sequence frame enables the user to provide in a sentence format those instructions which correspond to a selected output. Further the outputs are enabled to be selected in accordance with the descriptive names that have been applied to the outputs by a user.

As can be appreciated from screen 432 numerous action steps can be selectively added or deleted from a given sequence as desired by the user in response to the triggering event. It should further be understood that similar sequence frames are provided for e-mails which is a selected action step that can be taken in response to a triggering event. Further in other embodiments additional types of steps can be taken, each of which may have its own sequence frame which a user may populate with particular data to accomplish the carrying out of a particular action step. For example, additional actions may include repeating one or more steps in a sequence one or more times, and waiting for other actions or delaying for a time before

taking further actions. Similar principles are carried out in connection with the programming of the various types of sequences by the system of the exemplary embodiment.

Figure 49 shows a screen 438 which is associated with establishing a sequence in response to the detection of motion in the exemplary system. The motion set-up sequences enable a user to establish when detected motion within a particular area causes images to be captured and stored on a relatively permanent basis, and other actions to be taken as part of a sequence.

In screen 438, the cameras which are included in the system are presented using the descriptive naming terminology applied by a user. In response to the motion set-up screen 428 a user is enabled to select which sequences are enabled or disabled for particular cameras. In addition a user is enabled to access other screens for purposes of setting up selected detection areas in which motion is to be detected, as well as to configure the sequences that are executed in response to motion detection.

In response to selecting a set-up button for an appropriate camera from screen 438, a set-up screen showing a field of view currently obtained from the camera selected is displayed at the user terminal. An example of such a set-up screen is indicated for 440 in Figure 50.

Screen 440 includes a field of view of the designated camera generally indicated 442. The field of view of the camera includes the entire image field that the camera is currently viewing. Through use of a mouse or other input device, a user is selectively enabled to select one or more detection areas schematically indicated 444 within the field of view 442. The detection areas 444 are one or more areas to be analyzed and in which a determination concerning the detection of motion is to be made. An advantage of providing a selected detection area for

purposes of determining the presence of motion is that it avoids problems associated with monitoring in areas where motion may commonly be occurring in some areas, but where in other areas the occurrence of motion is an event for which images should be captured. In the exemplary embodiment the system is operative to compare the images only within the selected detection areas on an ongoing basis between the temporary captured images that are stored temporarily from each of the cameras. Comparison of the image in one or more successive ones of these temporary images are preferably analyzed through operation of the computer for differences. In this embodiment the computer operates to analyze the pixels which make up these images for a degree of change. If more than a set degree of change between one or more of these images which are spaced in time is detected, this is an image condition indicative and motion and a triggering event which causes the corresponding sequence to be executed.

An advantage of the exemplary embodiment shown in connection with screen 440 is that the user is enabled to selectively set the degree of change in the image in the detection area which will result in a determination that motion has been sensed. Specifically in the exemplary embodiment the user is enabled to selectively input values as to a percent of sensitivity which corresponds to a change in property such as intensity or color (or a combination of both) among pixels in the detection area that will be considered for purposes of determining whether motion has occurred. Likewise the user is enabled to set the percent of activity which corresponds to a quantity such as a number or percentage of pixels subject to analysis experiencing the set change in intensity or sensitivity which is indicative of motion. In this way the user of the system is enabled to set the motion detection parameters for the degree of change which will cause a

triggering event indicative of motion detection. A user may thereby avoid motion from being considered detected in circumstances where it is not desirable to capture images.

An exemplary embodiment of the invention includes a service program which enables a servicer or authorized user to test the suitability of the motion detection settings in particular circumstances. This program runs in one or more computers operatively connected to the camera of interest. The user inputs into the computer running the program the selected sensitivity and activity settings. The user may then cause activity to occur in the field of view of the camera. The program then causes a display to operate so as to indicate whether the activity resulted in motion being considered to have been detected. In this way a user may adjust the settings to suit their requirements. Alternatively the system may be operated in a test mode to capture a series of images from a selected camera. The settings may be applied by a test program to these captured images in a controlled manner to evaluate the settings versus the nature of image change. In an exemplary embodiment, captured images may be compared in the sequence originally captured or may be compared in a different sequence to determine the appropriate motion detection settings. Once selected, the selected settings for sensitivity and activity may be set in the system and applied on an ongoing basis.

Returning to the discussion of Figure 50, from screen 440 a user is enabled to display a schedule for selected days in which motion is to be detected. This is represented in screen 446 which is shown in Figure 51. Through inputs responsive to screen 446 the user is enabled to set the periods during which motion detection is accomplished for purposes of carrying out a sequence. As can be appreciated in many circumstances there are particular times of day during which motion is likely to be going on in a particular area and other times during which the

detection of motion may represent an usual event for which images should be captured. Through inputs of screen 446 an authorized user is enabled to selectively set the times during which motion detection analysis will be conducted.

From screen 446 a user is enabled to set the sequence that is carried out in response to a motion detection event. This is done in response to a screen 448 shown in Figure 52. Screen 448 includes the ability of a user to set the parameters associated with the detection of motion using the descriptive names for cameras which were set-up by the user. The user is also enabled to set the image quality parameters for the storage of images. In addition to parameters associated with other screens, in screen 448 the user is also enabled to set the number of images captured prior to the detection of motion which will be moved from temporary storage into relatively permanent storage in connection with images captured in response to the motion event. Using inputs directed to the "buttons" in screen 448, the user is also enabled to set up the sequence frames associated with cameras, outputs and e-mails by populating the information in the frame. A sequence frame enables the user to program using a sentence type structure, the actions which will occur in response to the triggering event. For example, in the sequence shown in 448 in response to motion being detected at the camera which watches the back door of a particular facility, the back door camera takes two images every second for sixty seconds. Thereafter the outside back light turns on for five seconds. In addition to capturing the images from the back door camera, two pre-alarm images are transferred from temporary storage into relatively permanent storage with data which describes the triggering event. Of course, it should be understood that the sequence parameters and actions are exemplary and in other embodiments other approaches may be used.

Embodiments of the invention also capture images in response to triggering events which are indicative of cameras being blocked. Such blocked camera events which are alternatively referred to herein as a lack of usable video, generally result from an image condition in which the image presented is either unduly light or dark, or otherwise lacking in contrast, not changing or otherwise appearing so as to suggest that usable video data is not being received. The sequence as associated with blocked cameras is configured in the exemplary embodiment with inputs responsive to a screen 450 shown in Figure 53. In response to presentation of the screen 450 a user is enabled to select the particular camera at which a blocked camera event will be detected.

In response to the user selecting a camera in response to screen 450, the exemplary embodiment displays a screen 452 shown in Figure 54. Through selections made in response to the presentation of screen 452 the user is enabled to set the blocked camera capability as either operative or inoperative. The user is also enabled to set up the criteria used for identifying a blocked camera as a triggering event and to configure the sequence that will be executed in response to the blocked camera event.

In response to a user selecting the set-up button from screen 452, the exemplary embodiment is operative to display a screen 454 shown in Figure 55. In screen 454 the user is enabled to set a brightness intensity (which may represent a color level tending toward white) as well as a darkness intensity (which may represent a color tending toward black). In this exemplary embodiment if the pixels which make up the field of view of a selected camera average above the selected brightness intensity, or alternatively average below the selected darkness intensity, a triggering event indicative of lack of usable video is initiated. Alternative embodiments may look for every pixel being above or below certain thresholds. Alternatively in

other embodiments of the invention the pixels which make up the field of view are analyzed by the computer on an ongoing basis for color level or contrast with pixels in other areas of the field of view. A failure of the image to have contrast above a set level for the overall field of view may in addition represent a triggering event indicative of lack of usable video. Of course, as previously discussed, other criteria may also be used for deciding that there is a lack of usable video.

Screen 456 shown in Figure 56 is presented to a user in the exemplary embodiment to set a time period during which the sequence will be carried out if a camera is blocked. The user is enabled to set the inputs for those times of day during which a blocked camera event will be considered a triggering event for the sequence to be carried out.

Figure 458 shown in Figure 57 is displayed in the exemplary embodiment to a user to configure the sequence that is executed in response to a blocked camera event. As in the other sequence configuration screens of the exemplary embodiment, a user is enabled to set the quality of the image data that is captured in response to the triggering event. Further the selection of “buttons” in the lower portion of the screen 458 causes sequence frames to be displayed which the user is enabled to arrange and populate with data to configure the sequence. As shown in Figure 58 the sequence frame 460 associated with sending e-mails is displayed. This sequence frame enables a user to input data identifying persons or groups of persons to which e-mails are to be sent. The ability to use the descriptive naming terminology defined by the user simplifies the programming of the sequences in the exemplary embodiment. Further as shown in screen 458 the user is enabled to employ other sequence frames such as sequence frame 462 which is associated with a camera. By populating the inputs for the camera sequence frame the user

creates a sequence which is carried out in response to the indicated camera being blocked. The exemplary sequence includes sending an e-mail to the e-mail group that is designated "security". In addition to sending the e-mail, camera #2 is operated by the computer to capture and store two images every second for twenty seconds. Of course it should be understood that camera number two is a camera which preferably includes in its field of view the camera that is indicated as blocked. Of course as previously explained in other embodiments, the programming for lack of usable video may also include the retention in more permanent memory of temporary images which were taken by the blocked camera prior to the lack of usable video being detected. Such images may indicate the cause of the lack of usable video. Of course other approaches may be used in embodiments of the invention.

In the exemplary embodiment of the invention device 330 is also configured to execute sequences in response to triggering events such as transaction steps which occur at automated banking machine 332 or cash register 344. In the exemplary embodiment sequences are configured to acquire images in response to the operation of transaction function devices. The images are stored in connection with transaction data regarding the transaction that is conducted at the machine. Figure 58 shows an exemplary screen 464 which is displayed to an authorized user by device 330 in connection with configuring sequences responsive to the operation of an automated banking machine. Through inputs in response to screen 464 a user is enabled to set up and configure the sequences associated with operation of the machine.

In the exemplary embodiment of the invention inputs responsive to screen 464 enable the user to set up the acquisition of images from particular automated banking machines. This is done through inputs to the user terminal in response to a screen such as screen 414 shown in

Figure 39. Further from screen 464 a user is enabled to configure the parameters for the acquisition of images in connection with particular events carried out at the ATM. This is accomplished in the exemplary embodiments through inputs through a screen 466 shown in Figure 59. Screen 466 enables a user to select triggering events for the capture of images. For example in the exemplary screen shown, the triggering events include the reading of a user's card and the printing of a receipt. The user is also enabled to configure the system to set the quality of the images stored based on the level of data compression used. Further as represented in screen 466, the user is also enabled to set sequences which include sequence frames for cameras, outputs and e-mails responsive to triggering events which occur in the course of a transaction. For example in exemplary embodiments of the invention the system may capture one or more images of a customer operating the banking machine so as to provide verification at a later date as to the identity of the particular person who has operated the machine to carry out the transaction. The number and character of images may be varied depending on transaction parameters including the transaction type, the time of day, the amount of money involved or other parameters associated with the user.

In the exemplary embodiment of the invention, transaction data is also stored in correlated relation with the captured image data. The image data is correlated with the transaction data by the particular time at which the transaction is conducted. Of course in other embodiments other approaches to correlating image and transaction data may be used.

Alternatively, image and transaction data may be stored together in common files depending on the requirements of the system. Generally, in the case of a system monitoring an automated banking machine, the transaction data that is stored will include parameters such as time, user

name, account number, transaction type and amount. The storage of these parameters in connection with the images enable the selective sorting of images by transaction parameters. This enables an operator of the system to more readily recover types or ranges of transactions that may of interest. In addition, it facilitates the selective retention or deletion of transactions in  
5 some embodiments by factors such as the transaction type and/or amount. Of course, in other embodiments other approaches may be used.

It should be understood that although in the exemplary embodiment image capture from an automated banking machine is conducted responsive to signals sent to transaction function devices on the system bus of the ATM, in other embodiments other triggering events may be  
10 used. For example, in embodiments of the invention the presence of a user adjacent to a transaction terminal may be sensed with a proximity sensor such as an ultrasonic detector or a weight sensing pad. Alternatively, automated banking machines may provide hard sensor inputs such as are obtained when a user receives cash from a cash receipt dispenser, or another device on the machine is moved. Such inputs may be configured as inputs to device 330 much in the  
15 manner of sensors 346. Such inputs may be used for purposes of configuring sequences in response to such inputs. For example a screen 468 shown in Figure 60 represents an example where an input from a sensor is used as the basis for configuring a sequence. Such an input may correspond to the operation of the device on an automated banking machine or other transaction terminal. Through inputs responsive to screen 468 a user is enabled to configure a sequence  
20 including capturing images from cameras, providing outputs or sending e-mails in response to such inputs. Of course, numerous other alternatives for accomplishing similar functions are encompassed within the scope of the present invention.

As previously discussed, a useful aspect of this form of the present invention is the ability to conduct searches for images that have been stored. Searches may be made based on one or more parameters. Image searching is accomplished responsive to selecting the icon 378 in the tool bar 370 displayed on numerous screens in the exemplary embodiment. A screen 470 shown in Figure 61 is used for obtaining user inputs concerning exemplary parameters that are employed in the searching of images. As can be seen in screen 470 a user is enabled to select time periods during which images are to be searched. The user is also enabled to select cameras which captured the image data which will be searched. The user is enabled to select all cameras or particular cameras which are to be searched. Alternatively, a user is enabled to select a “quick viewer option” which enables a user to scan through images in a manner that is later described.

Screen 470 also enables a user to select parameters for identifying images. These include for example selecting among images captured in response to particular alarm types as well as images captured in response to particular transaction types. In this way a user is enabled to selectively search the images for a number of different parameters. The ability to search by various parameters greatly reduces the effort required to identify images that may fit a user’s search criteria.

As explained in connection with other embodiments, image data may in addition be searched by visual characteristics. These may include for example searches for physical characteristics of persons shown in the images. Similarly searches may be made for certain types of apparel, certain colors or certain devices or items. The capability of the embodiments of the present invention may enable identifying particular persons or situations for which available data is otherwise incomplete. This may include for example identifying witnesses or other persons

present when particular circumstances have arisen. Of course numerous different types of criteria and parameters may be used in searching for selected images.

A further aspect of the exemplary embodiment represented in screen 470 is the ability to also group images by the particular type of event which has caused the images to be captured.

5 This provides the capabilities of allowing a person reviewing images to catalogue and review images by the triggering event which caused them to be captured together. This may provide a user with additional insights as to particular events. It may also enable a user to search an event type of most interest first before moving onto other images which meet search criteria.

In response to the conduct of searches, various image pages are displayed by the device  
10 330. Examples of image pages are shown in Figures 62 through 72. Each of these image pages shows one or more images that have been captured and stored, and which are displayed in response to search requests. The nature of each of the image pages and how they are used in the exemplary embodiment are explained in detail in the charts shown in Figures 73 and 74. Of course it should be understood that in other embodiments of the invention other image pages may  
15 be used.

It should be noted that in the exemplary embodiment of the invention, a control panel schematically indicated 472 is displayed in connection with image pages. A control panel 472 enables a user to perform various functions to review images, as well as to download images from device 330 to other terminals in the system with a greater degree of assurance that the  
20 images have not been tampered with. It should also be noted that in image pages of the exemplary embodiment a graphical representation of a piece of movie film is included to

represent to a user that a series of images were acquired at high frequency in response to an event so as to acquire a film clip that approximates full motion video.

A further aspect of the present invention that is useful is the ability of the system to indicate that a plurality of images have been captured in response to certain triggering events.

5 This is indicated by the image sets as represented for example in Figures 64 and 65. Further as represented for example in Figures 67 through 70, particular images may be selected for enlargement for review by a user with information concerning the nature of the triggering event which resulted in the capture of the image. A listing of the data which is included with triggering events and which can be recovered by an authorized user of the system is listed in the chart in  
10 Figure 75. A further useful feature of the exemplary embodiment is the capability of a user to provide comments concerning particular images. Such comments may be input from the user terminal via typed input in text form. In alternative embodiments, a user may input comments by voice to text conversion input as well as to have comments stored as a voice file. Such comments may be useful later in recovering images when searching by particular comment  
15 criteria. The computer may itself be programmed to add comments to particular fields in connection with images depending on the programming of the system.

The control panel 472 used in the exemplary embodiment is shown in greater detail in Figures 76 through 80. The control panel 472 includes a plurality of icons and indicators as well as an image counter which is shown in Figure 77. The function executed in response to selection  
20 of each of the icons in the control panel when particular image pages are being displayed is shown in detail in Figures 78 through 80. As will be understood from the detailed description, the control panel 472 enables a user to navigate through images in a rapid and selective manner.

The user is also enabled to navigate through a series of images sequentially in varied increments and directions within the series of selected or displayed images. Further as represented in Figure 80, the user is enabled to provide inputs to the control panel so as to identify images captured within certain time parameters. It should be understood that in embodiments of the invention the series of images may be considered to be one dimensional. However in other embodiments the images may be arranged in a matrix or other multilayer or multidimension format based on varied parameters. By making selections and inputs users may navigate in varied directions in the series of images.

Figures 81 through 83 show numerical examples of the capability of the control panel 472 in enabling a user to navigate through a series of images which are displayed to a user. As represented graphically in each of these figures the selection by the user enables the user to find an image of interest to enlarge it, mark it and to print those images which are of interest.

A further useful aspect of the exemplary embodiment of the invention is the ability of a user to identify selected images for downloading from device 330 to another terminal which is connected thereto. Such downloading may be accomplished in a manner which provides greater assurance that the downloaded images are not altered. This is accomplished in the exemplary embodiment using a feature which is referred to as an image cart. In reviewing images, a user is enabled to click on a rectangular icon adjacent to images so as to change the color thereof. As represented in Figure 84 these rectangular icons change color responsive to selection so as to place the images in the image cart. The positioning of these icons relative to images can be seen for example in displayed images represented in Figures 62 through 64. When scrolling through the images using the control panel 472 the user is selectively enabled to click on those images

that they find of interest for purposes of downloading by changing the color of the image cart symbol 474 adjacent to the image of interest. As explained in Figure 78 a viewer icon 476 may be selected at any time on the control panel to enable a user to quickly view those images that they have included in the image cart.

5           A further useful aspect of the exemplary embodiment of the present invention is the ability to transfer the images in the image cart from the device 330 in a manner that provides greater assurance that the images have not been subject to tampering. In the exemplary embodiment of the invention a user is enabled to download images using the image cart feature to a terminal. However device 330 is programmed so as to include in connection with such  
10 images a warning to indicate to the viewer thereof that the image was not secure and may be subject to tampering. Given the ability of current computer equipment to do image modification and manipulation, this feature assures that images which are downloaded without security give any user thereof fair notice that the image may not be as originally captured. This notice is preferably sent with the downloaded image when the data corresponding thereto is transferred to  
15 the user terminal and the image is output on a display thereof.

The image cart feature however enables the application of a digital signature with images downloaded in the image cart along with the associated data. This security feature is attained by selecting a key icon 477 in the control panel as shown in Figure 78. In response to selection of the key icon 477 a user downloading images is presented with a screen of the type shown in  
20 Figure 85. The screen advises the user that the images are being downloaded as a secure file to assure integrity. In addition the user is provided with a password which must be input to unlock the package of image and transaction data which has been secured with the digital signature. In

the exemplary embodiment, the images are also downloaded with an encryption scheme which is integrated with the digital signature technique to assure that only the authorized user may access such images. Of course it should be understood that this technique is exemplary and in other embodiments other approaches to encrypting the data as well as techniques for reducing the risk that images have not been subject to tampering may be used.

Thus the new transaction record system and method of the present invention achieve the above stated objectives, eliminate difficulties encountered in the use of prior devices and systems, solve problems and attain the desirable results described herein.

In the foregoing description certain terms have been used for brevity, clarity and understanding, however no unnecessary limitations are to be implied therefrom because such terms are used for descriptive purposes and are intended to be broadly construed. Moreover, the descriptions and illustrations herein are by way of examples and the invention is not limited to the exact details shown and described.

In the following claims any feature described as a means for performing a function shall be construed as encompassing any means known to those skilled in the art as being capable of performing the recited function and shall not be deemed limited to the particular means shown in the foregoing description or mere equivalents thereof.

Having described the features, discoveries and principles of the invention, the manner in which it is constructed and operated, and the advantages and useful results attained; the new and useful structures, devices, elements, arrangements, parts, combinations, systems, equipment, operations, methods, processes and relationships are set forth in the appended claims.
